development of reconstructive surgery of the ear. Progress has been particularly rapid during the past decade since the use of the surgical microscope has become widespread. When one considers that the ossicles of the ear are the smallest bones of the body and that their measurements in many instances are in fractions of a millimeter, one can understand the extreme care necessary while operating in this region. This care is feasible when visualization of the area is adequate. Dr. Guilford* is one of the leaders in the development of otologic surgery in the United States. Many of the techniques in wide use are the result of his efforts and experience.

As a result of the improvements in surgical techniques, surgical treatment of chronic disease of the middle ear is now advised at a much earlier stage than it was a few years ago. If adequate surgical treatment is given prior to destruction of the middle-ear structures, the risks of complication and of permanent hearing loss are greatly reduced.

Maternal Rubella

The Need for Early Identification of Hearing Loss.

As is well known, maternal rubella in the first trimester of pregnancy can cause multiple congenital defects. Outstanding examples of these defects are sensorineural hearing loss, cataracts, heart defects and mental retardation. Throughout the nation, health care professionals are becoming aware of the frightening number of these defects resulting from the rubella epidemic of the early 1960's.

There is a great need for early identification of the children with a congenitally acquired hearing defect. The sooner the hearing loss is recognized, hopefully by age six months to one year, the better chance the child has of obtaining maximum benefit from a structured habilitation program for language and speech development.

Recent advanced otolaryngologic and audiologic diagnostic techniques have made early identification of hearing loss in very young children a reality. For example, cortical audiometry* in conjunction with standard otolaryngologic and audiologic procedures allows an early and accurate estimation of the hearing in these children. With this information an early program can be started; amplification can be so utilized that these children are not deprived of critical auditory input in the developmental years of language and speech. All physicians who have contact with rubella infants must be aware of the necessity for early hearing examination. Observation without definite diagnosis throughout the critical age period of twelve to twenty-four months when language perception and speech should be developing is bad medical practice. Children so neglected will have to compensate later for the time interval when they lacked auditory input. Unfortunately, some children never completely recover this lost opportunity.

Etiology of Skin Cancer

The terms "cancerous," "benign," "malignant" are used glibly and often. In fact, no entirely satisfactory definitions are applicable to all the varieties of tumors and tumor-host interactions.*

The skin should be an ideal tool with which to clarify concepts of cancer. The most accessible "organ" of the body, it is also prone to develop malignant tumors. This may relate to its role as protective barrier against the surrounding environment.

*See Peterson, W. C., Jr.: Precancer and Cancer of the Skin. Minnesota Med 51:483, 1968.

No one, as yet, understands how environmental factors induce malignant change. Actinic keratoses, leukoplakia, and arsenical keratoses are examples of "premalignant" skin tumors which may be produced by environmental factors. "Premalignant" indicates a significant probability that these benign tumors will become malignant. Estimates of this probability vary but are mostly in the range of 20 to 30%. There is no sharp line between the malignant and the benign lesion. Malignant transformation in these "premalignant" tumors probably begins in one cell, which then multiplies at a faster rate than the surrounding normal cells and displaces them. The transformed cells transmit the "malignant character" to daughter cells; therefore we may assume that a basic genetic change has taken place.

Study of genetic factors may help to delineate the causes of skin cancer. The nevoid basal-cell carcinoma syndrome, an autosomal dominant trait, affects several tissues. In the skin multiple basal-cell carcinomas develop at an early age. The clinical and histologic appearance of these tumors does not differ from the ordinary non-heritable basal-cell carcinomas. In xeroderma pigmentosa, a rare familial skin disease with an autosomal recessive mode of inheritance, extreme sensitivity to sunlight begins in early childhood. There follows severe degenerative changes in the skin with development of squamous-cell carcinomas, basal-cell carcinomas and melanomas.

Keratoacanthoma is a rapidly growing skin tumor which may be difficult to differentiate histologically from squamous-cell carcinoma. The nature of keratoacanthoma is not understood. Calling it a "pseudocancer" only clouds the issue. Is this tumor benign or malignant? Is containment and destruction of the tumor due to host factors, or to some intrinsic factor in the tumor itself, or to both?

The rising incidence of skin cancer may be due to an aging population and to increasing exposure to actinic and other forms of radiation. This makes further study and understanding imperative. Beyond this, study of skin cancer should help to illuminate tumor-host interactions and the effects of environmental and genetic factors.

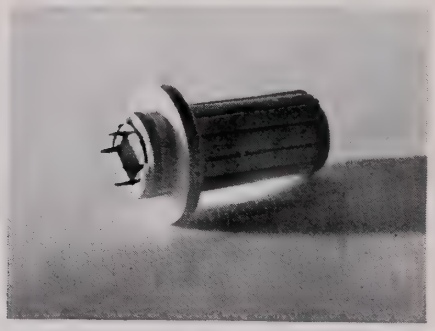
Pharyngo-Esophageal Dysfunction

Dr. Kirchner's* discussion of pharyngo-esophageal dysfunction is indeed excellent. Inasmuch as he is a noted laryngologist, it is not surprising that his principal emphasis is on the pharyngeal and upper esophageal phases of deglutition. He stresses the importance of distinguishing organic lesions, such as tumors, strictures, and diverticula, from neurologic, neuromuscular, and functional disorders related to the hypopharynx and the cricoid sphincter. Dr. Kirchner describes the symptoms that characterize the various types of upper esophageal and pharyngeal dysphagia and the importance of accurate observation of the patient's behavior during deglutition. The findings on inspection of the throat are described in detail. In most cases, the nature of the disorder can be suspected from the history and clinical observations.



Dr. Kirchner calls attention to the role of manometric studies, which we have found so very useful in elucidating the physiology of deglutition and the mechanisms of the various neuromuscular disturbances of the esophagus and the esophagogastric sphincter. The techniques for making these determinations have been refined, and such manometric studies are now performed routinely in our evaluation of swallowing disorders. Although esophageal motility studies have been used primarily in the evaluation of disturbances of the esophagus and lower sphincter, they are indeed applicable to the upper sphincter and hypopharynx. Such disorders as "achalasia of the cricoid" and "the hypertensive cricoid sphincter" can be recognized with the pressure recorders that are used for these studies.

A brief reference was made by Dr. Kirchner to endoscopic examination of the pharynx and esophagus. Although such examinations are

essential to detect organic lesions, they are certainly of less value in the evaluation of neuromuscular disorders involving the esophagus and the sphincters. We have found that the passage of bougies over a previously swallowed thread is a valuable diagnostic technique in such neuromuscular disorders. The type of resistance that is encountered will help to determine the nature of the disturbance, and this procedure is sometimes very valuable in the treatment of various esophageal abnormalities.

The Editor's Soliloquy

Tiger by the Tail

The heart is a pump. It possesses no physiologic, endocrine, biologic function, as other vital organs do. Furthermore, it is without doubt biologically inferior to the life-sustaining blood which it propels throughout the body; and as an organ it is infinitely less complex than many of the other organs which it keeps alive by its relentless pumping action for an average of 68 years.

There are some mystical notions about the heart being the center of life—the citadel of the *elan vital*,* as it were, because when it stops beating, life terminates abruptly. If, however, its pumping function could be taken over by a mechanical apparatus, this surrogate organ might conceivably provide a few years' moratorium on death.

Since successful heart exchange between two homogeneous individuals receives and apparently requires no nerve connection to the recipient, future studies might well be directed to a pumping mechanism rather than a pumping muscle, thus eliminating the reflex autonomic obstacle as well as the sensitive moral issues involved. After all, non-reactive materials are already available for replacing diseased vessels, and the interposition of a mechanical pump should not constitute an insurmountable obstacle.

Kletschka et al.** have devised a prototype of a mechanical heart which is somewhat smaller than the chest cavity and does not destroy blood cells. It remains for him and his associates to perfect this model, reduce it to the size of a normal heart, install within it a long-lived or rechargeable power source and electric motor, and perhaps create a systolic-diastolic impulse with capacity to maintain a relatively normal blood pressure. It would appear that the mechanical difficulties of perfecting such an instrument would be far fewer and simpler than those involved in anticipating and controlling the numerous unpredictable biologic, physiologic and immunologic imponderables of installing and maintaining a muscular heart, whether homogeneous or heterogeneous.

Electroencephalographic tracings have demonstrated cessation of brain function even though the heart continues to beat and respiration is being artificially maintained. It is conceivable that under these circumstances many other bodily functions could continue as long as circulation is maintained. But without evidence of cerebral function should these other processes be continued? Heretofore, when the electroencephalogram has revealed no evidence of life in the brain, both the medical profession and the clergy have been content to consider the motor turned off.

Reliance on a donor entails too many complex problems: biologic, immunologic, physiologic, legal, social, moral and religious, when one is waiting for nothing more than a pump. This does not gainsay, however, that experimental studies should not be done on both homogeneous and heterogeneous heart transplantation, with all their variable and intangible somatic responses to the nth power. Unless an unforeseen breakthrough occurs or an unpredictable immunologic-biologic-physiologic phenomenon develops, it can be predicted that thousands of experimental hours and millions of dollars will be expended before the solution of a perfect heart transplant is obtained.

---

*See Test Your Word Score Page 797.

**Kletschka, H. D., et al.: Artificial Heart. Minnesota Med 51:11 and 51:191, 1968. Also see page 787.

Nevertheless, studies should be conducted concurrently in all three of these areas: mechanical, homogeneous, and heterogeneous restoration of heart function, each study to be pursued freely and exhaustively.

Barnard and Shumway have already conducted independent clinical trials that have not been futile, despite their high mortality. Further clinical studies must be continued, but the public should not be allowed to become so optimistic by way of undue publicity as to expect revolutionary changes in the cure of cardiac disease within a decade.

Investigators will be flooded with volumes of praise and criticism; they will be simultaneously anathematized as fiends and eulogized as saints. They must be able to withstand the damaging effects of both. They must seek neither fame nor fortune. They must persevere single-mindedly despite frustration and failure and leave it to history to assess and evaluate their achievement.

History tells us that medical scientists have had a tiger by the tail before; true scientists live on, securely and honorably immortalized in medical annals, while the charlatans, the quacks and the pseudoscientists are interred with their fortune, their notoriety, and their bones.

Carl O. Rice, M.D.

Old Doc Hess says: She has to go to church on Sunday now and then just to keep even with those who go every Sunday and probably don't mean it.

President's Letter Continued from Page 757.

those who occupy a full-time position in a hospital as Directors of Medical Education or Directors of Department of Medicine or Surgery. These men, although they are for the most part academically trained, are more like the old time Clinical Professor, but unlike him they do not have the disadvantages of a burdensome practice. These Directors will have time for reading and research, and for teaching. They will be experts in Clinical Medicine and Surgery.

If there has been a misunderstanding between the full-time medical school teacher and the practitioner, there may be even more between the practitioner and the full-time hospital teacher. However, neither can get along without the other. If the medical staff resists the full-time surgeon, it will soon find the hospital deteriorating. If the full-time educator does not understand the problems of his staff, he too will suffer.

Let us hope that this new breed of educator will flourish and that the full-time medical school educator, the full-time hospital educator, and the profession itself can function together with patience and understanding. From this accord will result better medicine for all the people.

Wallace P. Ritchie, M.D., President
Minnesota Academy of Medicine

Remedies for Erysipelas

For erysipelas a liniment of bears' grease is used, that from the kidneys in particular; fresh calves' dung also, or cow-dung; dried goats' milk cheese, with leeks; or else the fine scrapings of a deer's skin, brought off with pumice-stone and beaten up in vinegar. Where there is redness of the skin attended with itching, the foam from a horse's mouth is used, or the hoof, reduced to ashes.—Pliny

Curbstone Consultation

Central Venous Pressure

QUESTION: Monitoring of the central venous pressure has found its place as a very valuable method for the clinical management of patients. Can you outline some of the limitations in its use?

ANSWER: Even assuming that one uses the method in a technically proper manner there are certain limitations of which one should be aware. It is very valuable in assessing the relationship that exists between blood volume, cardiac competence, and vascular tone. However, it is important to bear in mind that a specific ventricular function curve exists for a particular circulatory state. For example, in a case in which the myocardium is compromised, a given central venous pressure will be associated with a smaller ventricular stroke work than in the case of a normal myocardium. Thus a venous pressure of 8 cm water in a normal heart may indicate the same balance between cardiac competence and effective blood volume as does a much higher venous pressure in a borderline compensated heart.

A healthy heart may decompensate with pulmonary edema at a lower central venous pressure than a diseased heart. Serial venous pressures are more valuable than isolated readings. The function of the right ventricle is more reliably assessed by the central venous pressure than that of the left ventricle. The central venous pressure may be misleading when hypovolemia coexists with (or even precipitates) cardiac failure with a rising venous pressure. The increased venous return may lead to improved cardiac function. Central venous pressure readings may also be unreliable when mechanical obstructive states exist, such as mediastinal compression from tumor masses, venous thrombosis, and cardiac tamponade. Changes in intrathoracic pressure such as occur in cases of flail chest, pneumothorax, hemothorax, or positive pressure breathing may result in changes in the central venous pressure in such a way that the readings no longer reflect a measurement of the underlying state of the heart, blood volume, or vascular tone.

Harold D. Kletschka, M.D.
Houston, Texas

He was a simple soul who had not been introduced to his own subconscious.—John Galsworthy

---

It seems to me as if not only the form but the soul of man was made to walk erect and look upon the stars.—Bulwer

The Grey, Creeping Death

During the colonization of Asia and Africa the Europeans brought with them syphilis, to inspire later the unpleasant but not unjustified phrase: "Civilization means syphilisation."

The first wave of this new disease which swept across Europe in its virulent form was highly contagious and often fatal. . . . After a quarter of a century the disease changed its nature. It grew milder and its course was slower and more superficial. . . . Down the generations the disease lost more and more of its original virulence and malice. A small hard tumour, a swelling of the glands and after a few weeks a rash, no more serious than the measles—that was all. . . . As a result the fear of the disease abated. People ridiculed the precautionary measures and looked upon syphilis as a childhood disease which everyone had to suffer before he became a real man. The result was an overwhelming increase of syphilis in the seventeenth century, particularly in France. It was the so-called age of gallantry, and syphilis was called the "gallant sickness." It was "good form" to have it.

But sooner or later it took its toll. It ate away the victim's skin leaving putrid discoloured ulcers, particularly on the throat and the top of the head, making the hair fall out and leaving ugly scars.

The fashion of the age took this into account. It introduced the wig to disguise the baldness, created the jabot, which hid the ulcers on the neck under costly pleated lace, and made the wearing of gloves *de rigueur* to cover the hand sores with elegance and also to protect from possible infection by a handshake. The man of the Rococo age covered his whole body up to his chin and he had every reason to do so. Any blemishes on the face were covered with layers of powder and paint, and where this was of no avail with "beauty patches." The extravagant costume of the Rococo with its flowing periwigs and voluminous skirts was a white-wash to hide the syphilis.*

*H. S. Glasscheib, M.D.: The March of Medicine, 1964. Also see page 774.

Kidney Stone Surgery on the Frontier

Doctors took out kidney stones too. Dr. Hillary Ryan, Galveston, Texas, had a patient who had passed a squirrel tail into his urethra. A large stone had formed around the tail where it was lodged in the bladder. With three boys assisting, the doctor cut into the perineum with a pocket knife and removed a stone an inch in diameter. A second operation was necessary.

"We passed the director into the bladder and made an incision into the urethra," reported Dr. Ryan. "Passed a probe in, as before, and made the cut in the same direction, to the left of the rectum. As soon as the cut would permit the finger to pass into the bladder, the director was withdrawn, and the finger used. The opening was enlarged very slowly and carefully until we had extended it for about two inches and a half; we then, with some difficulty, drew out a stone one inch and a half thick by three and one-half inches long, and in it the squirrel's tail, of about five inches in length, one and one-half inches bent back on itself. It was in a good state of preservation and looked very much like salted meat." The patient recovered quickly.*

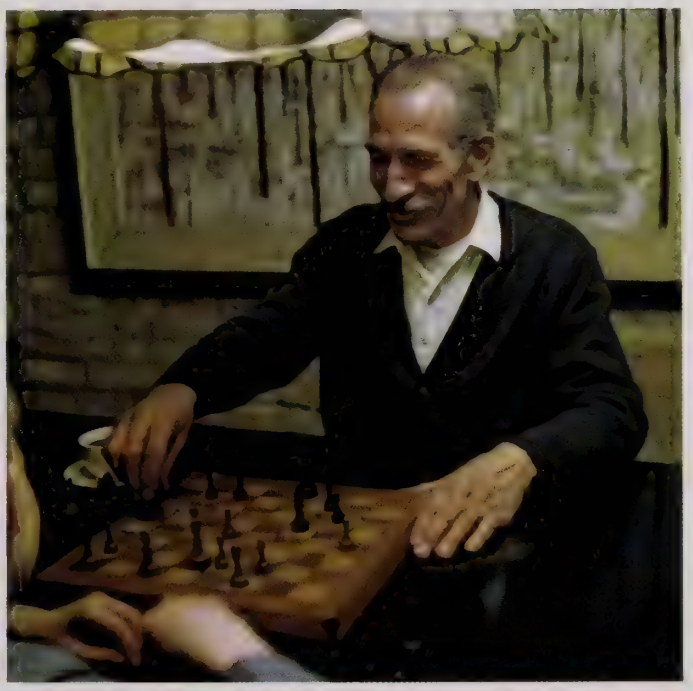
People who are much older than they look seldom have much intelligence.—G. C. Lichtenberg

Now . . . a new
alternate salicylate product
from Warren-Teed

Magan®
(magnesium salicylate, W-T)



magan®

an alternate salicylate

particularly offered for the management
of those chronic arthritic and rheumatic
patients with gastrointestinal intolerance
to aspirin and other salicylates

pain relief comparable to aspirin

Magan may provide effective salicylate therapy for a substantial number of your patients who cannot tolerate other salicylates because of gastrointestinal irritation.

Magnesium salicylate is recognized as a safe and effective alternate to aspirin. A controlled clinical study showed Magan to be not significantly different from aspirin as an analgesic in the treatment of arthritic patients.[1]

Reports from a private practice experience study indicate that Magan was tolerated by a high percentage of patients judged by their physicians to be unable to take aspirin or other salicylates due to gastrointestinal intolerance.[2]

1. Stern, S.B.: Med. Times, Oct. 1967
2. Reports on 1200 patients, data in files, Warren-Teed Pharmaceuticals, Inc. 1966

(See next page for prescribing information)

A different salicylate structure—
with no coating, no buffering
and it is sodium free

magan®
(Magnesium Salicylate, W-T)

microphotograph of magnesium salicylate crystals

Composition: Each orange-colored compressed tablet contains 5 grains (approximately 325 mg.) of magnesium salicylate, W-T (salicylic acid equivalent 75%).

Actions, Indications, Uses: The analgesic, anti-inflammatory, and antipyretic effects of MAGAN are similar to those of aspirin and other salicylates. Accordingly, MAGAN is indicated for the treatment of rheumatoid arthritis, osteoarthritis, nonarticular rheumatism such as bursitis, painful-shoulder syndrome, tendosynovitis, fibrositis, and other musculoskeletal disorders. The drug is also useful for the symptomatic relief of pain, aches, and discomfort of headache, neuralgia, minor injuries, dysmenorrhea, common cold and other minor infections of the respiratory tract. MAGAN (Magnesium Salicylate) may be tolerated by some persons intolerant to aspirin by reason of gastrointestinal irritation.

Contraindications: Because of the danger of hypermagnesemia, MAGAN is contraindicated in cases involving advanced chronic renal insufficiency. MAGAN, as other salicylates, may counteract the effect of uricosuric agents, and should not be prescribed for patients on such drugs.

Warning: As with all salicylates, high dosages of MAGAN should be avoided entirely or administered with caution to patients with liver damage, preexisting hypoprothrombinemia, vitamin K deficiency, and before surgery.

Adverse Reactions and Precautions: The same precautions applicable to salicylate therapy in general should be followed in prescribing MAGAN. Appropriate precautions should be taken in prescribing MAGAN for persons known to be sensitive to salicylates. If reaction develops, drug should be discontinued. Dosages of anticoagulants should be reduced with the administration of high dosage levels of MAGAN. *Impaired Renal Function:* Appropriate precautions should be taken in administering MAGAN to patients with any impairment of renal function including discontinuing other drugs containing magnesium and monitoring serum magnesium levels particularly if dosage levels of MAGAN are high. *Salicylate Poisoning:* Symptoms of salicylism, resulting from high doses of MAGAN, can be expected to resemble closely in character and intensity those associated with aspirin poisoning. These range from dizziness, drowsiness and ringing in the ears to vertigo, convulsions, coma and hypokalemia. Salicylate poisoning can be treated by intravenous fluids with sodium bicarbonate or lactate and potassium supplementation. In very severe cases, hemodialysis may be necessary. Vitamin K, 5-20 mg. orally or slowly i.v., usually restores the prothrombin time to normal.

Dosage: Adults 1 or 2 tablets every 4 hours as required with a full glass of water. In arthritis and other rheumatic conditions, higher doses may be used at the discretion of the physician. The experience with MAGAN in children is limited. The drug should not be used, therefore, for patients below 12 years until indications for use and dosage have been established.

How Supplied: Bottles of 250 and 1000 tablets.

WARREN-TEED PHARMACEUTICALS INCORPORATED
COLUMBUS, OHIO 43215
SUBSIDIARY OF **ROHM AND HAAS COMPANY**

Distinguished Service in Minnesota

The presentation of certificates and pins to Minnesota physicians who have engaged in the practice of medicine for 50 years has become an impressive highlight of each Annual Meeting. According to custom the presentations are made during the course of the Annual Banquet. Few who have witnessed these ceremonies soon forget the setting of such an occasion at which these colleagues with a half century of medical practice to their credit so alertly respond to the roll call.

The custom of honoring Minnesota physicians who have served their patients and communities for a half century was established in 1942. Forty-one physicians were honored at the first ceremony. This group also included those who had passed the 50-year mark prior to 1942.

To be eligible for this award a doctor must have spent the majority of his 50 years practicing medicine in Minnesota.

In 1968 seventeen doctors were added to the membership in this distinguished club.*

*See page 774: Senior Peers.

Richard E. Anderson, M.D.

Doctor Richard Anderson says he always had the ambition to be a doctor. After a business college course he became timekeeper in a large factory, and later a telegrapher. This gave him an opportunity to work nights, and to attend school days. Although he held many jobs while pursuing his education, he obtained high school, B.S. and M.D. degrees in eight years.

One of his most memorable days was when he delivered five babies in a day, all in farm homes, with no modern equipment and only a family to help.

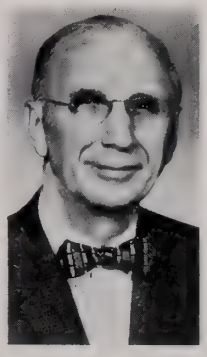
His most interesting case was a patient who had a Staphylococcus septicemia. This occurred when the sulfa drugs were only on trial use to clinics. He was able to obtain some. After sulfa, 22 blood transfusions, 29 abscesses drained, and months in hospital, the patient recovered.

During his practice in Willmar, Doctor Anderson has conducted a busy general practice, performed many operations, and managed a private hospital for 15 years. And he has managed to do so while running a farm, participating in outdoor activities, and enjoying the company of his helpful and understanding wife.

Herbert H. Busher, M.D.

Doctor Herbert Busher was born in Sioux Falls, South Dakota, where his father was a minister. He was no ordinary student and at an early age declared to his father that he did not wish to enter the ministry but instead would like to become a doctor. After graduating from Concordia College, Dr. Busher went to the University of Minnesota where he graduated from Medical School in 1919. After a year of interning at the University Hospital, Dr. Busher completed a surgical residency and immediately thereafter opened offices in the Lowry Medical Arts Building. He died January 26, 1967.

Isabell L. Cameron, M.D.



Doctor Isabell Cameron decided to become a doctor when she was ten. Why? Because her mother, a determined New Englander, informed her she was to become a physician. By 1918, she reached her goal and interned in Boston during the influenza pandemic of that year. After serving two years as an obstetrical resident, she entered general practice where her obstetrical experience served her well.

She remembers a bitterly cold winter night when she delivered a premature three-pound infant, warmed him in blankets, surrounded him with hot water bottles, and took him by car to St. Barnabas Hospital, where room rates were then one dollar a day. The child survived. Doctor Cameron says her role in practice was to treat, advise, and sympathize with those who needed her.

Woodard L. Colby, M.D.

Dr. Woodard Colby spends his leisure hours pursuing his hobbies of gardening, farming and bird watching. He is a graduate of the Minnesota University Medical School and has worked at Ancker, Lindsay, Gillette and the Shriners Hospitals. In addition to the University of Minnesota, Dr. Colby did graduate work at Harvard and Vienna. His specialty is pediatrics and he was an Assistant Clinical Professor of Pediatrics at the University of Minnesota. Dr. Colby is a former Vice President and President of the Ramsey County Medical Society.

Harold S. Diehl, M.D.

Doctor Harold Diehl decided to study medicine because he felt that the practice of medicine would be interesting, challenging and an opportunity to be of service to people. As his father was a minister his family background probably contributed to this feeling.

His most interesting and satisfying experience—although hardly a "case problem"—was the privilege of assisting in the development of a distinguished medical school at the University of Minnesota: one that is nationally and internationally respected for its undergraduate teaching, its graduate training programs and its contributions to medical research.

His major hobby has always been and still is work, interesting work, including writing. An important supplement to this is the time he spends at his summer cottage on Star Island, Cass Lake, Minnesota.

His favorite medical preaching, has probably been that physicians have an obligation not only to care for the sick but also to do everything possible to prevent disease, both personally and as community leaders.

Besides serving as dean of the medical school for 23 years at the University of Minnesota, Doctor Diehl became senior medical officer of the American Cancer Society. That society credits him with starting the events that led to the report by the Surgeon General of the U.S. Public Health Service on the dangers of smoking.

Frederick A. Figi, M.D.

Since retiring from the active staff of the Mayo Clinic about ten and a half years ago, Doctor Frederick Figi and his wife have traveled a good deal. But his chief interest now is woodworking, and he has converted his basement recreation room into a shop where he spends much of his time.

Here are excerpts from a Rochester Post-Bulletin article—"Retired Plastic Surgeon is Wood Hobbyist."

"Dr. Figi has always been interested in highly polished hard woods but not until retirement did he have ample time to work with them.

"He has had woods shipped back from his travels to West and South Africa, South America and Mexico, as well as stops on the couple's world tour in 1957-58. A number of former patients have sent him generous portions of exotic woods from remote foreign areas.

"In 1961 Dr. Figi was featured in the Post-Bulletin for his cane collection. He now has more than 300 canes and walking sticks of various shapes and uses collected over a period of 37 years."

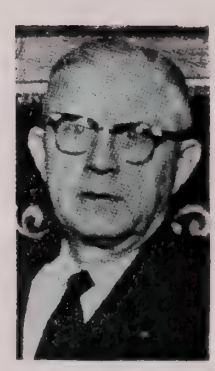
While woodworking is an all-absorbing hobby for the retired physician, Doctor Figi assures us that it falls far short of the gratification and sense of accomplishment afforded by the practice of medicine.

Albert Fritsche, M.D.

Doctor Albert Fritsche took up medicine because it was in his family. His father, the late Doctor L. A. Fritsche, sent four sons through medical school. The younger Doctor Fritsche started practice in New Ulm in 1919, and what sticks in his mind are the cases like the following which he had in his first two years of practice.

One dark night he entered a strange farmhouse to deliver a child. When he entered the room, a hysterical pregnant woman stood in the bed. She flung herself at his feet. While relatives restrained her, he gave chloroform and managed to deliver a child that was in a breech position.

Later he and his father consulted on the case of a 58-year-old woman who experienced abdominal pain one month before and then ran a fever. When she became short of breath, they detected dullness in the chest. They resected a rib, and entered a pus cavity that contained 12 gallstones.



Doctor Fritsche handled these and similar cases without the help of laboratory and x-ray facilities.

Joseph N. Gehlen, M.D.

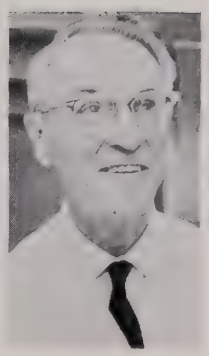
Doctor Joseph Gehlen obtained his medical education at Creighton University in Omaha, Nebraska. Born in Lemars, Iowa, Dr. Gehlen came to Minneapolis in 1921 to accept a position with the Minnesota State Board of Health. He is presently associated with Dr. C. N. Hensel in the practice of internal medicine in the Central Medical Building in St. Paul.

Dr. Gehlen was chief of the tuberculosis service at Anker Hospital in St. Paul for many years.

Silas W. Giere, M.D.

The earliest medical experience of Dr. Silas Giere's life occurred at age 3, when his father took him by long train ride from his country parish to St. Paul. There a doctor and nurse gave him sweet-smelling perfume (chloroform) and comforting words, then removed his tonsils. This experience made him feel "that's for me" and in the ensuing years confirmed his resolution to become a doctor.

The experience he remembers best was one night when a snowstorm raged. At 10:30 p.m. a phone call precipitated "the doctor" on a drive behind horses, to a maternity case across the prairie, cutting fences, rolling out of the sleigh several times, stopping in a farmyard to repair a breakdown of the sleigh, arriving at 6:00 a.m., delivering the baby, and returning home at noon. This was one of many similar experiences.



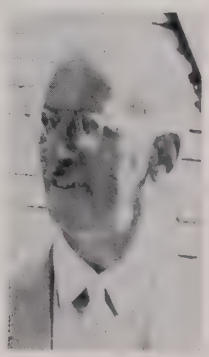
His outstanding day occurred in Lower Antilles. There the whole city turned out at the small airport in early days when his cable for reservations was confused by local officials, and the local populace came to the airport to meet Greer (Garson).

His most mysterious case was a thought-to-be drunk upon whom he performed a successful tracheotomy with a dirty knife, as he lay on the floor, cyanotic. Apparent cause? A bee sting while haying.

Since leaving the Department of Pathology at the University of Minnesota, Dr. Anderson C. Hilding has been in Duluth carrying on both the practice of Eye, Ear, Nose and Throat and investigative work, the latter occupying his full time. Through these years, interspersed with this work, has been an academic year in Vienna, two years at the Mayo Clinic, a year as Visiting Research Professor in Otolaryngology at Columbia, and a winter session in India doing eye surgery at a Mission Station.

One of his outstanding experiences was the thrill of presenting a research paper with his son (Associate Professor of Ear, Nose and Throat at Yale) in which both spoke before the 1966 American Laryngological Association Meeting in Puerto Rico.

On the lighter side, one of his most memorable surgical experiences occurred in the Emergency Room when a group of plump, middle-aged inebriated, overly-dressed women presented themselves and one of their number claimed to have swallowed a candle stick. She indicated the general region of the larynx and said that at a party she had taken a bite of birthday cake. He began to anesthetize her throat with cocaine solution, meanwhile trying to dodge the resulting rivers of alcohol and stomach contents. He was using a small swab on a long, curved, wire applicator in the laryngeal pharynx, when it seemed that the patient grasped it with her pharyngeal muscles and there was some resistance in pulling it out again. To his amazement, when he laid the swab on the table, something had been added—the tip of the swab had entered the opening of a coiled wire candle stick, such as were found in the candy flower candle-holders used to decorate birthday cakes of that era. The intern, leaning over his shoulder, commented, "Gosh, doctor, you did that neatly." The patient, when she saw it, stood up and raised her fists as high as she could reach, proclaiming, "..... ....., ... didn't I tell you girls I swallowed a candle stick!"



Anderson C. Hilding, M.D.

Instead of talking of his life since graduation, Dr. Charles Lick prefers to report this case: Forty-four years ago a young woman came to his office because of a tumor of the distal end of her right radius. There had been a minor injury a few weeks before. After the injury, a small nodule appeared and grew rapidly. Dr. Lick recommended amputation on the basis of the biopsy which Dr. A. T. Bell interpreted as giant cell sarcoma.

The husband refused an amputation and accordingly only the distal end of the radius was removed. The wound healed and some time later a leather support was used to hold the hand in position.

In 1968 the patient returned to the office of Dr. Lick still in good health with no recurrence of the tumor. A review of the slide from 1924 showed a giant cell tumor—a tumor not generally recognized as benign until Jaffe's work in the 1940's.

Dr. Lick is happy to report that this was one instance in which the husband's advice for this radical treatment proved to be better than his own.

Charles L. Lick, M.D.

Thomas A. Lowe, M.D.

As a farm boy, Doctor Thomas Lowe decided early to be a doctor He worked hard, finished high school in three years with honors and then worked through seven years at the University of Minnesota. During those years, he was in turn a butcher, livery man, drayman, cream hauler, elevator tender, shoe shiner, paper seller, junk dealer, house-to-house salesman, farm hand, dishwasher, furnace keeper and waiter on tables.

He left medical school and went overseas in World War I with the Mayo Base 26. There he assisted surgeons in a 20,000 bed hospital. Once he took care of 65 fractured legs at one time. When the war was over, he volunteered for rehabilitation work in Serbia and was in charge of a hundred-bed hospital. The government decorated him twice and recommended him as Chief Surgeon of a 300-bed hospital with the rank of Major. He declined, came home, and took refresher courses before practice.

He did general practice but preferred surgery. He was formerly in group practice with the late Dr. Earl Lowe and is now in practice with his nephew Dr. Alex Lowe, at the same location for 42 of his 50 years.

Dr. Lowe is a fellow of the International College of Surgeons and a fellow of the Industrial College of Surgeons, a member of the American Medical Association, Minnesota State Medical Association and the Ramsey County Medical Society.

He gets up early, sees his hospital patients early, and walks a mile before opening the office. He had many hobbies early in life but has bypassed them for work. He was lucky in marriage, has one daughter, a son-in-law and three grandchildren. He has good health, a strong constitution and a busy practice people kindly give him.

Donald McCarthy, M.D.

Doctor Donald McCarthy divides his life in medicine into three periods. The first began in 1919 when he was discharged from active duty with the Navy. He started to practice internal medicine in Minneapolis as an assistant to Dr. J. G. Cross for three years. Then he entered his own practice, sharing office space with Dr. Henry. This first period ended in 1941, when he again entered the service, this time as a Junior Medical Officer at the Naval Hospital, Great Lakes, Illinois. He served successively as Senior Medical Officer of the Minneapolis Recruiting Station, Chief of Medicine on the U.S. Hospital Ship "Relief" in the Atlantic and Pacific, as Chief of Medicine and Executive Officer of the Naval Hospital at Great Lakes, and as Senior Officer at the Naval Operating Base at Midway Island.

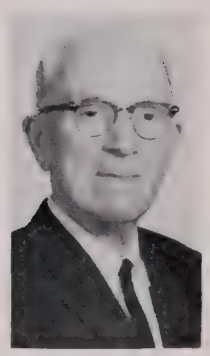
The last period—the Administrative Period—commenced in 1946 when he entered the Veterans Hospital system as a Deputy Area Medical Director. He supervised veterans' hospitals and clinics in the North Central States until he retired in 1965. When that event occurred, he accepted an administrative position at the Minnesota Department of Health, a position he still occupies on a part-time basis.

Christian L. Roholt, M.D.

Doctor Christian Roholt of McIntosh, Minnesota, tells that he inherited his urge to care for the sick from his mother and father. After he graduated from the University, he started to practice and eventually had his own hospital in Waverly, Minnesota. The two cases that he remembers most vividly were both women. One was brought to his office nearly dead from uterine bleeding. Because of her desperate condition, he gave intravenous saline, and then removed her uterus: she survived. The other patient was a newlywed who told him she would die when she delivered her first child. To reassure her, he spent the night with her while she was in labor. After an easy delivery, she began to fail rapidly and died at 5:00 p.m. the same day. Besides these two cases, Dr. Roholt recalls most vividly the day he examined and cared for 64 patients.

Lloyd H. Rutledge, M.D.

Doctor Lloyd Rutledge left high school, went to Kansas City, and afterward into the business world. After eight months on a salary of $12.00 per week, he quit and enrolled as a premedical student at the University of Missouri.



Why medicine? First, his father was a country doctor in a small town; second, from his view from a small room in a Kansas City rooming house, the business world looked too tough.

He transferred to the Minnesota University for two reasons: first, a Fellowship in anatomy under Dr. Jackson furnished $550.00 a year to help pay expenses; second, the Mayo Clinic was affiliated with the University of Minnesota.

After medical school, he had a chance to practice at Detroit Lakes for the summer of 1919 as a seasonal job while he waited for a Fellowship to open at the Mayo Clinic. But after summer nights, canoe rides, a girl named Nancy, the golf course and the walleyed pike, he began to like northern Minnesota. Then came the wild rice and the duck shooting, not hunting but shooting, and he forgot about the University and Minneapolis. The town needed a new doctor and a hospital. He drove a car, a team and sled, shovelled carloads of snow, delivered babies at 5:00 A.M. in the country, shot 10 ducks and got back to the office by 10:00 A.M.

His most interesting case was in the 1920's when he ran into a typhoid-like case, but the woman had a little red streak on her hand from cleaning a young cottontail rabbit. After three weeks—no diagnosis. Further requests for blood were refused. A consultant, Dr. W. H. Long of Fargo, suggested rabbit fever. A few minutes after she died, he drew the blood, and the first case of tularemia in Minnesota was reported.

But I have not given up the ducks and the golf—not yet, thank God!

Virgil J. Schwartz, M.D.

Doctor Virgil Schwartz, born in Romania in 1894, came to Minneapolis at six and graduated from the University of Minnesota Medical School in 1919. He trained at the University and General Hospital in ophthalmology and otolaryngology. Then in 1923, after spending about a year abroad in the field of bronchoesophagology, he began to practice in Minneapolis. During his 40 years of practice, he wrote numerous articles, and had "through sheer luck, the opportunity to report five or six medical entities which had not previously appeared in literature."

Doctor Schwartz' family particularly enriched his life. During his training at Minneapolis General Hospital he met and later married Mary L. Dean. They had one daughter and two grandchildren. Doctor Schwartz and his wife shared interests in music, literature, drama, opera, current affairs, travel, and sports.

James F. Weir, M.D.

Dr. James F. Weir, a Mayo Clinic staff member for 33 years, head of a section of medicine, and chairman of four sections of medicine, was born of farm parents in Byron, Ontario, in 1893. He graduated in medicine from Western University in London, Ontario, in 1918, and was an officer in the Royal Canadian Army Medical Corps in England in 1918 and 1919. He interned at the University of Minnesota Hospitals for eight months in 1919 and 1920.

Dr. Weir came to Rochester, Minnesota, in 1920 as a fellow in medicine in the Mayo Graduate School of Medicine; he was appointed to the staff of the Mayo Clinic in 1925. He became an instructor in medicine in the Mayo Graduate School of Medicine in 1925 and was advanced to assistant professor in 1933 and to associate professor in 1944.

A gastroenterologist, he helped develop intravenous therapy for the dehydration and hypochloremia of pyloric obstruction, and he showed how vitamin K could be used to control hemorrhage in the jaundiced patient. His acumen and mastery of physical diagnosis caused him to be known as the "physician's physician."

"I have no clear idea of why I entered medicine," he has said, "but farming did not interest me. Educational facilities were available in the area in which I grew up, and some acquaintances there had taken up medicine. I suppose I did so because they did.

"Success in the practice of medicine involves many things. Of these, the history the patient gives is the most important. Take your time, listen carefully. Thus I was trained, thus I practiced, thus I preached."

He reports that the outstanding event in his career "was the occasion when I was elected president of the staff of the Mayo Clinic for 1949, an honor which was wholly unexpected and was sincerely appreciated as an expression of the esteem of my colleagues."

He was married to Miss Edna E. Enke of Rochester in 1921; he and Mrs. Weir have two daughters. He devotes his spare time to studies on the genealogy of his and Mrs. Weir's families, and to cabinet work at his home in Rochester.

The Viewing Box

An Unusual Case of Bilateral Obstructive Uropathy

The two x-rays shown here are from intravenous pyelogram studies taken two months apart on a six-year-old male child. The first study appears on the left. It was obtained three months after the patient was hospitalized for a neck mass diagnosed as reticulum cell sarcoma. He was treated surgically, followed by radiation therapy, and then placed on intravenous cyclophosphamide.* Following discharge, the patient was continued on the drug orally. He did well until he experienced the sudden onset of hematuria, dysuria, urgency and frequency. A urine culture was sterile and the first intravenous pyelogram (Figure 1) showed bilateral hydronephrosis and ureteral dilatation down to the bladder, which was noted to be markedly contracted and irregular in contour. It was felt that the upper tract changes may well be secondary to bladder spasm. Two months later, a repeat intravenous pyelogram (Figure 2) was performed which showed not only normal upper urinary tracts but a normal bladder outline also.

What is your diagnosis? (See next page.)

*Cytoxan (Mead Johnson).

Figure 1

Figure 2

Diagnosis—Cyclophosphamide Hemorrhagic Cystitis.

The above condition was considered a strong possibility when this patient developed his urinary tract symptomatology; so the drug was discontinued and the patient maintained on forced hydration. The remission was spontaneous and the recovery complete as evidenced by the second intravenous pyelogram film (Figure 2).

Cystitis is a relatively common occurrence in patients who are undergoing cyclophosphamide therapy, and it may develop after either intravenous or oral administration of the drug. Usually with intravenous administration, the symptomatology occurs in 24 to 48 hours, but it may take a month or more before the condition is manifest when the drug is taken orally. The condition is characterized by dysuria, urgency, frequency and hematuria, and the urine culture is characteristically sterile.

Cystoscopy reveals a hyperemic, edematous bladder with many areas of hemorrhage but, after withdrawal of the drug, the symptoms usually subside in four to five days, with complete resolution by two months.

Prolonged use of the drug in the face of the hemorrhagic cystitis may produce chronic fibrosing cystitis with exsanguinating hemorrhage.

Patients receiving Cytoxan* should therefore be followed carefully for symptoms of bladder irritation. In most cases discontinuation of the drug and forced hydration will be sufficient for controlling the condition.

Robert D. Bugby, M.D.*
Edina, Minnesota

*Department of Radiology, Fairview-Southdale Hospital.

The Progress Notes of Hippocrates

In Larissa, a man, who was bald, suddenly was seized with pain in the right thigh; none of the things which were administered did him any good. On the first day, fever acute, of the ardent type, not agitated, but the pains persisted. On the second, the pains in the thigh abated, but the fever increased; somewhat tossed about; did not sleep; extremities cold; passed a large quantity of urine, not of good character. On the third, the pain in the thigh ceased; derangement of the intellect, confusion, and much tossing about. On the fourth, about noon, he died. An acute disease.—Hippocrates

Medical Seminar

The Platelet in Hemostasis

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

WRIGHTS' HYPOTHESIS of the origin of blood platelets as fragmented portions from the cytoplasm of the megakaryocytes of the bone marrow is generally accepted. These platelets or thrombocytes are small non-nucleated structures measuring 2 to 4 μ in diameter and arise from the adult megakaryocytes, the largest of all normal marrow cells, measuring 50 to 150 μ in diameter. By volume measurements it has been estimated that 4,000 platelets are produced from a single megakaryocyte.[2]

Over the past several years, advances in platelet physiology and biochemistry have shown platelets to be viable cell fragments requiring and producing energy for their major function in hemostasis. It is their activity and unique metabolism in normal spontaneous hemostasis that will be discussed.

Morphology

When examined in the capillaries, platelets appear as small, round, or oval disks. In vitro they may maintain this appearance in a suitable ionic environment and in the presence of colloids, but usually become spherical with numerous spiny processes protruding from their surfaces. They may then assume triangular, quadrangular, crescent, dumbbell, or other bizarre and irregular forms. Pseudopodia or dentritic processes are numerous if the smear is made on a nonwettable surface, but are not seen when the smear is made directly on a glass slide. When observed by time-lapse cinematography, the platelets as they leave the vessels can be seen to throw out filamentous dendritic processes which are wide at their bases. As one of these projections touches a glass slide, it sticks to the surface and enlarges; other dendrites also become fixed. The cell then becomes completely adherent to the slide and is usually round with a central granular area, or granulomere, and a clear surrounding area or hyalomere. These platelets are often referred to as spread or resting forms.[3]

Ultrastructure

Details of platelet ultrastructure after osmic acid fixation and ultrathin sectioning, as seen with the electron microscope, have been observed. The cell membrane is 5 to 8 mμ thick; fifty to 100 oval homogeneous granules 0.15 to 0.25 μ in diameter and encompassed by a thin membrane have been described. Mitochondria with few cristae are present, similar in size to that of the granules. The hyaloplasm contains numerous tubules and microvesicles, as well as siderosomes, the ferritin-containing structures.[4,5]

The major biologic activities of blood platelets will be discussed in the following sections.

Adhesiveness and Aggregation

If an arteriole or venule is transected under direct microscopic observation, adhesion of platelets to the edges of the cut vessel is seen to occur within seconds. The specific force that draws the platelets to the denuded vascular surface is not known. The phenomenon has

been called platelet "stickiness." It has long been known that platelets in certain instances adhere to foreign organic particles such as yeast, some microbes, and on organic surfaces such as glass barium sulfate and alumina.[6]

Electrostatic Potential

Recent observations suggest that an electrostatic potential may be a factor, since it has been shown by electrophoresis that platelets carry a net negative charge. Sawyer and Pate,[7] by applying a small electrical current to a blood vessel wall, were able to initiate the formation of a platelet thrombus at the site of a positive but not a negative current. Although adhesion on the basis of a difference in electrostatic charge is an attractive hypothesis, it has some defects. Blood cells other than platelets normally bear negative charges too, but do not adhere to damaged blood vessels and cannot be interchanged for platelets. Some have maintained that the difference between other blood cells and platelets may be due to differences in ionic groups in the cell surface[8] or to differences in cell size,[9] thus adhesion due to electrostatic force is still a possible explanation. Recently it was shown that the collagen connective tissue to which platelets adhere has an electrophoretic mobility* similar to that of platelets.[10]

Selective Affinity

From these studies, therefore, adhesion does not seem to be a simple matter of unlike surface attraction. It became apparent that platelets adhered not to injured cells, but rather to intercellular junctions and to areas denuded of endothelial cells.[11] More recent studies have shown that there is a selective affinity of connective tissue for platelets. Using ground fragments of aorta, Bounameaux[12] noted that there was no adhesion of platelets to endothelial cells, but observed their immediate agglutination to fibers apparently of vascular connective tissue origin. Others noted that when animal mesentery was traumatized and then subjected to platelet-rich plasma, aggregation of platelets occurred only in the traumatized tissue and to the elastic and collagen fibers.[10,13] Zucker and Borrelli[14] demonstrated that collagen was the tissue component to which the platelets adhered; and they confirmed this observation by showing that collagenase destroyed the activity of the connective tissue suspension. These observations have been confirmed by electron microscopic studies, which show that in platelet plugs occurring at the site of a transected arteriole the platelets adhere to the perivascular connective tissue and not to the endothelium.[15] It appears then that platelets do not normally adhere to endothelium and intercellular substance; but that platelet adhesion occurs only when the endothelial cells are traumatized and underlying collagen connective tissue is uncovered.

Platelet Cohesiveness

Subsequent reactions involve platelet cohesiveness. Under normal conditions, when platelets have adhered to collagen fibers, new platelets soon aggregate to these fixed platelets and to each other, forming platelet clumps. Agglutination of platelets in vitro has been induced by various means, and at times spontaneous clumping of platelets has made study difficult. Cooling increases the cohesive property of platelets, as do certain heavy metals.[16] Clumping occurs in the presence of heparin. Platelets are also aggregated by antigen-antibody complexes, polystyrene particles, latex particles, bacteria, viruses, uric acid crystals, and many other agents including fibrinogen preparations. Glynn and co-workers[17] showed that when platelets in citrated platelet-rich plasma were exposed to particulate matter such as latex particles, the platelets phagocytosed the particles.

There are, however, two agents which physiologically seem to act in platelet cohesion. The first of these is thrombin, which has long been known to clump platelets rapidly, with an apparent loss of platelet integrity as seen by light microscopy.

The effect of thrombin on platelets has been called *viscous metamorphosis.*** Viscous metamorphosis is initiated by thrombin probably produced by the extrinsic or tissue thromboplastin system. The thrombin, acting with fibrinogen adsorbed to the platelet's surface, as well as with that present in the surrounding plasma in the presence of calcium and magnesium, contributes to this process. During this

*See Test Your Word Score Page 797.

**The term "viscous metamorphosis" was originally used by Eberth and Schimmelbusch[18] in 1886 to describe changes in single platelets. The term is used to refer to such a wide variety of clotting processes that it has almost lost its usefulness. In present-day studies the terms platelet "aggregation," "agglutination," "clumping," "cohesion," and "fusion" tend to be used.

viscous metamorphosis there occur a degranulation of the platelets and the release of serotonin, biogenic amines[19] (histamine, catecholamines), adenosine diphosphate, inorganic phosphate, platelet factor 3, free amino acids, potassium, acid phosphatase, and other constituents.[20] Although platelets appear to be fused into an amorphous mass during viscous metamorphosis, the electron microscopic studies by Kjaerheim and Hovig[15] showed that the platelet membranes are preserved without apparent breakdown of gross platelet structure. The viscous change previously observed by light microscopy therefore represents tight adherence of platelets without actual fusion. During viscous metamorphosis additional thrombin is generated via the intrinsic or plasma thromboplastin system, and growth of the platelet aggregate ensues. Viscous metamorphosis, once initiated, thus ensures its own propagation.

The second agent causing platelet cohesion was discovered in erythrocytes in 1960[21] and identified as adenosine diphosphate.[22] It had previously been known that platelets contained high concentrations of adenosine triphosphate, which disappeared with platelet aggregation. Since adenosine diphosphate is the first breakdown product of adenosine triphosphate, these observations suggested that the increase in adhesiveness brought about by adenosine diphosphate might underlie the physiologic mechanism responsible for the formation of hemostatic plugs. This hypothesis is now supported by considerable evidence.

The Factor of Aggregation

Born[23] has made the following observations regarding aggregation by adenosine diphosphate: (1) It is found in all animal species in which it has been looked for. (2) It is effective, rapid, and highly specific. (3) It does not involve dephosphorylation of adenosine diphosphate. (4) It requires calcium and at least one plasma protein, almost certainly fibrinogen. (5) It is reversible. (6) It is involved in aggregation caused by other agents including thrombin, fatty acids, catecholamines, and collagen.

Born[23] has further emphasized that aggregation by adenosine diphosphate can be inhibited in the following ways: (1) by deficiency or inactivation of a component of the platelets, (2) by deficiency or inactivation of the plasma protein, (3) by lack or excess of ionic calcium, (4) by elimination of adenosine diphosphate by the action of enzymes, and (5) by certain substances related to adenosine diphosphate, specifically its breakdown products, adenosine monophosphate and adenosine.

The mechanism of adenosine diphosphate aggregation is not known. *One hypothesis suggests* that a complex composed of adenosine diphosphate, calcium, and a plasma protein, perhaps the von Willebrand factor, makes bridges connecting adjacent platelets.[24] *A second hypothesis is* suggested by Born, who feels that bombardment by adenosine diphosphate molecules may cause a configurational change in a protein on the platelet surface, and that this change is required for the formation of disulfide bonds between platelets and molecules of fibrinogen. Evidence in favor of Born's hypothesis is that (1) in the presence of adenosine diphosphate the platelets swell before they aggregate, (2) there is minimal or no binding of adenosine diphosphate to the platelets, and (3) aggregation but not swelling is inhibited by substances that block sulfhydryl groups and by others, such as dimercaprol and dithiothreitol, which tend to preserve sulfhydryl groups intact or break disulfide bonds.[23] The aggregation of platelets in vitro by adenosine diphosphate is inhibited by adenosine, and more strongly by 2-chloroadenosine.[25] It has been proposed that an enzyme system in the platelets and plasma constantly reestablishes adenosine monophosphate-adenosine diphosphate ratios capable of inhibiting platelet aggregation, thus preventing a self-extending process.

Salzman[26] has proposed yet a *third hypothesis for the mechanism* of platelet aggregation. He has noted that the addition of adenosine diphosphate to platelet-rich plasma leads to breakdown of the adenosine diphosphate through stepwise dephosphorylation to adenosine, which then is incorporated by the platelet. He theorizes that the presence of adenosine diphosphate in the platelet environment inhibits the splitting of adenosine triphosphate to adenosine diphosphate by platelet membrane

ATPase. Salzman suggests that the platelet membrane ATPase normally keeps the platelet in an unsticky state and maintains the cell size and shape. He feels that adenosine diphosphate inhibits the platelet membrane adenosine triphosphatase, resulting in platelet stickiness by exposing adhesive sites and permitting platelet aggregation to occur through intermediate secondary bridges containing calcium, fibrinogen, or other proteins. Spaet and colleagues[27] object to this hypothesis on the grounds that it fails to account for the extremely minute concentrations of adenosine diphosphate that are effective in aggregating platelets, for such amounts do not inhibit adenosine triphosphatase-adenosine diphosphate conversion. They feel that the concentration of adenosine diphosphate that actually reaches platelets in platelet-rich plasma is probably significantly less, since the plasma adenosine diphosphatase is capable of effecting considerable adenosine diphosphate breakdown en route. From the foregoing discussion it is obvious that the mechanism of platelet aggregation is unsettled.

As mentioned previously, serotonin (5-hydroxytryptamine) is released from the platelets during the process of viscous metamorphosis and may assist further aggregation, as well as produce local vasoconstriction. In support of this concept is the observation that parenteral serotonin reduced the blood loss of cut rat tails without affecting the bleeding time.[28] There remains some conflict in the literature, however. Studies by Salzman[29] in rabbits treated with reserpine to deplete serotonin showed no prolongation of the bleeding time. When similarly treated rabbits were also given heparin, the bleeding time was prolonged. These observations are in keeping with the concept of the hemostatic triad in which vasoconstriction, platelet aggregation, and blood coagulation act conjointly in producing hemostasis. A combined defect of these activities would therefore be necessary to explain the prolonged bleeding. Serotonin alone does not seem crucial in human hemostasis, since serotonin-depleted patients rarely have a hemorrhagic disorder.

The Platelet and Blood Coagulation

It is known that a platelet plug can temporarily arrest bleeding. Hemostasis, however, is not complete until the platelet plug is reinforced by a fibrin clot. To contribute to their function in hemostasis, blood platelets contain materials active in blood coagulation. Whether the platelets produce these factors, or whether they merely act as sponges acquiring the factors from the surrounding plasma, has not been determined. Two types of platelet clotting factors have been distinguished according to their localization and origin:[30] those that are adsorbed from the plasma onto the platelet surface and those that are a part of the platelet structure.

Platelet Factor 1

The following plasma clotting factors are those felt to be adsorbed to the platelet: fibrinogin (I), II, V, VII, VIII, IX, X, XI, XII, and XIII. Elution studies have shown a variability in the tightness of adhesion of these various factors.[30] Of note is the fact that platelet factor 1 is probably adsorbed plasma factor V. There remain three platelet factors and probably a fraction of the platelet fibrinogen. These are felt to be "true platelet factors" and a part of the platelet structure.

Platelet Factor 2

Platelet factor 2 accelerates the conversion of fibrinogen to fibrin by thrombin and has been called "thrombin accelerator" or "fibrinoplastic factor."

Platelet Factor 3

Platelet factor 3 is a lipoprotein in which the active lipid components appear mainly to be phosphatidyl serines and phosphatidyl ethanolamines. Deutsch and Lechner[30] state that the lipid portion can easily be separated from the protein part by extraction with lipid solvents, and they note that these lipids can substitute for the whole platelet factor 3 in almost all coagulation tests. Both platelet granules and surface membrane contain the lipoprotein.[19] In intact platelets the lipoprotein is not available for clotting. However, it is theorized that during viscous metamorphosis there is a reorientation of the platelet surface lipids, as well as a release of granules. It is further speculated that factor 3, thus made available, reacts to form intrinsic prothrombin activator which is important for the induction of the first phase

of clotting at the site of the platelet plug.[31] In addition, Spaet[10] postulates that the reoriented platelet surface lipids possibly provide a surface capable of initiating clotting by activating Hageman factor (factor XII).

Platelet Factor 4

Platelet factor 4 is a protein or high molecular weight polypeptide that is believed to be a component of the hyalomere. Its function of directly neutralizing heparin was initially suspected from the clinical observation that patients with a reduced number of platelets have an increased sensitivity to heparin. Recently it has also been shown to interfere with the action of fibrinogen breakdown products.[32]

Intrinsic Platelet Fibrinogen

Intrinsic platelet fibrinogen was suspected when it was shown that platelet extracts clotted if thrombin was added. Studies in the last two years by Castaldi and Caen[33] have shown that adsorbed fibrinogen could be removed by intensive washings. If the platelets were then disrupted, the platelet fibrinogen was again found in the extracts.

The Platelet and Clot Retraction

Roskam[6] in 1961 reported that, on direct microscopic observation of in-vivo hemostasis, new platelets were constantly being added while others were constantly being dislodged by the stream of flowing blood from the initial friable platelet aggregation.

Platelet Retraction

As this initially loose platelet aggregate enlarges, it is converted into a compact hemostatic plug by the platelet's ability to retract. This may occur within a few minutes. The ability to shrink to a solidly fused mass was found to be due to a contractile protein in platelets called "thrombosthenin." Thrombosthenin constitutes approximately 15% of the total protein of platelets and is an actomyosin similar, in some respects, to muscle actomyosin. Both muscle and platelet contractile proteins contract or superprecipitate at low ionic strength in the presence of adenosine triphosphate and magnesium ions. Both also have adenosine triphosphatase activity, splitting a phosphate group from adenosine triphosphate to form adenosine diphosphate. Like muscle actomyosin, the adenosine triphosphatase activity of thrombosthenin is activated by magnesium ions and, to an even greater extent, by calcium ions. Muscle actomyosin differs from thrombosthenin both in its immunologic properties and in the dynamics of its adenosine triphosphatase activity.

Clot Retraction

Clot retraction was found to be inversely proportional to the fibrinogen content of the red cell mass, since the more red cells and fibrin in the clot, the less it can contract. It has been shown that clot retraction is an energy-consuming reaction requiring intermediate glucose metabolism and producing lactic acid. What initiates the clot retraction is not known, but Spaet[10] suggests that it may be triggered by the action of thrombin. He showed considerable increased compactness of a platelet aggregate after exposure to thrombin for one minute. Platelet cohesion after this type of exposure to thrombin remained and resisted washing after 30 minutes of incubation. He noted considerable dispersion in a similar platelet aggregate without thrombin exposure; after a gentle saline wash only adhesion remained.

Platelets and Vascular Integrity

It is felt by many observers that platelets participate in some way in the preservation of vascular integrity. Increased vascular fragility has long been recognized in cases of prolonged and severe thrombocytopenia. Kramár[34] by using various methods of platelet suppression, was able to show a striking parallel between decreased platelet count and decreased capillary resistance, and he concluded that the vascular bleeding tendency resulted from a specific association of the two factors: low capillary resistance and platelet deficiency. Witte[35] demonstrated that in experimental thrombocytopenia there is increased vascular permeability to fluorescein-labeled proteins. Viable platelets were labeled with ^{35}S and injected into thrombocytopenic rats[36] and into normal pigs;[37] and later the ^{35}S label could be demonstrated in the blood vessel walls. Certain observations indicate that it does not require the presence of viable platelets to improve vascular integrity. Patients with thrombocytopenic purpura have shown improved vascular integrity when given

lyophilized platelet material. Klein and colleagues[38] noted that this effect occurred without elevation of the platelet count. They speculate that hemostasis and vascular integrity may not necessarily depend on morphologically intact, circulating platelets, but may be related to separable components. Others have failed to demonstrate an improvement in hemostasis unless the infused platelets were viable.[39] What the specific components are and how they participate in maintaining vascular integrity remain to be demonstrated.

Hemostasis in Larger Vessels

The foregoing discussion was concerned mainly with the platelets' ability to effect hemostasis by forming a platelet plug in small vessels. Defects in larger vessels are also influenced by platelet action. The initial platelet aggregate or white thrombus initially slows blood flow and further acts as a nidus around which fibrin is deposited. The fibrin, which is laid down as a network of dense strands, then adds to the local trapping of blood cells with the establishment of a red thrombus, thus sealing the defect in the larger vessel. Platelets therefore appear to participate in hemostasis no matter what the caliber of the vessel.

Summary

Blood platelets have been discussed as viable cell fragments with a dynamic metabolism whose major function appears to be in hemostasis. Major biologic activities of platelets are those concerned with adhesiveness and aggregation, blood coagulation, clot retraction, and vascular integrity.

Bedlam

Bethlem* Royal Hospital began as a priory** in 1247 of the Order of the Knights of the Blessed Mary of Bethlehem. Like Bridewell, it was handed over to the City of London by Edward VI, but as an asylum and not an almshouse. There were soon more lunatics than the old priory could hold and so in 1676 a new Bethlem was built. For over 200 years it was one of the sights of London. On paying an admission fee of one penny, which went to the upkeep of the hospital, anyone could spend all day wandering round the hospital and laughing at the lunatics. Bethlem was first of all famous and finally notorious for the brutal ill-treatment meted out to the inmates. Everyone knew the hospital as "Bedlam" and the word has passed into common usage for designating any madhouse or even any scene of uproar.†

Abbott Antihypertensive Building Blocks

A simplified approach to the practical management of hypertension

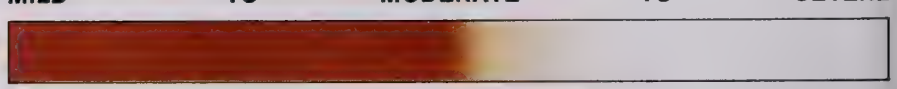
Enduron: (methyclothiazide) A basic building block for mild hypertensives

Excellent day-long Na^+ output, yet easy on the K^+

Enduron provides an excellent starting therapy. Your patient's sodium excretion is greatly enhanced. Yet potassium loss is low.

The therapeutic action is smooth, and persists for a full 24 hours. With Enduron you can prescribe convenient once-a-day dosage without skimping your patients on day-long thiazide effectiveness.

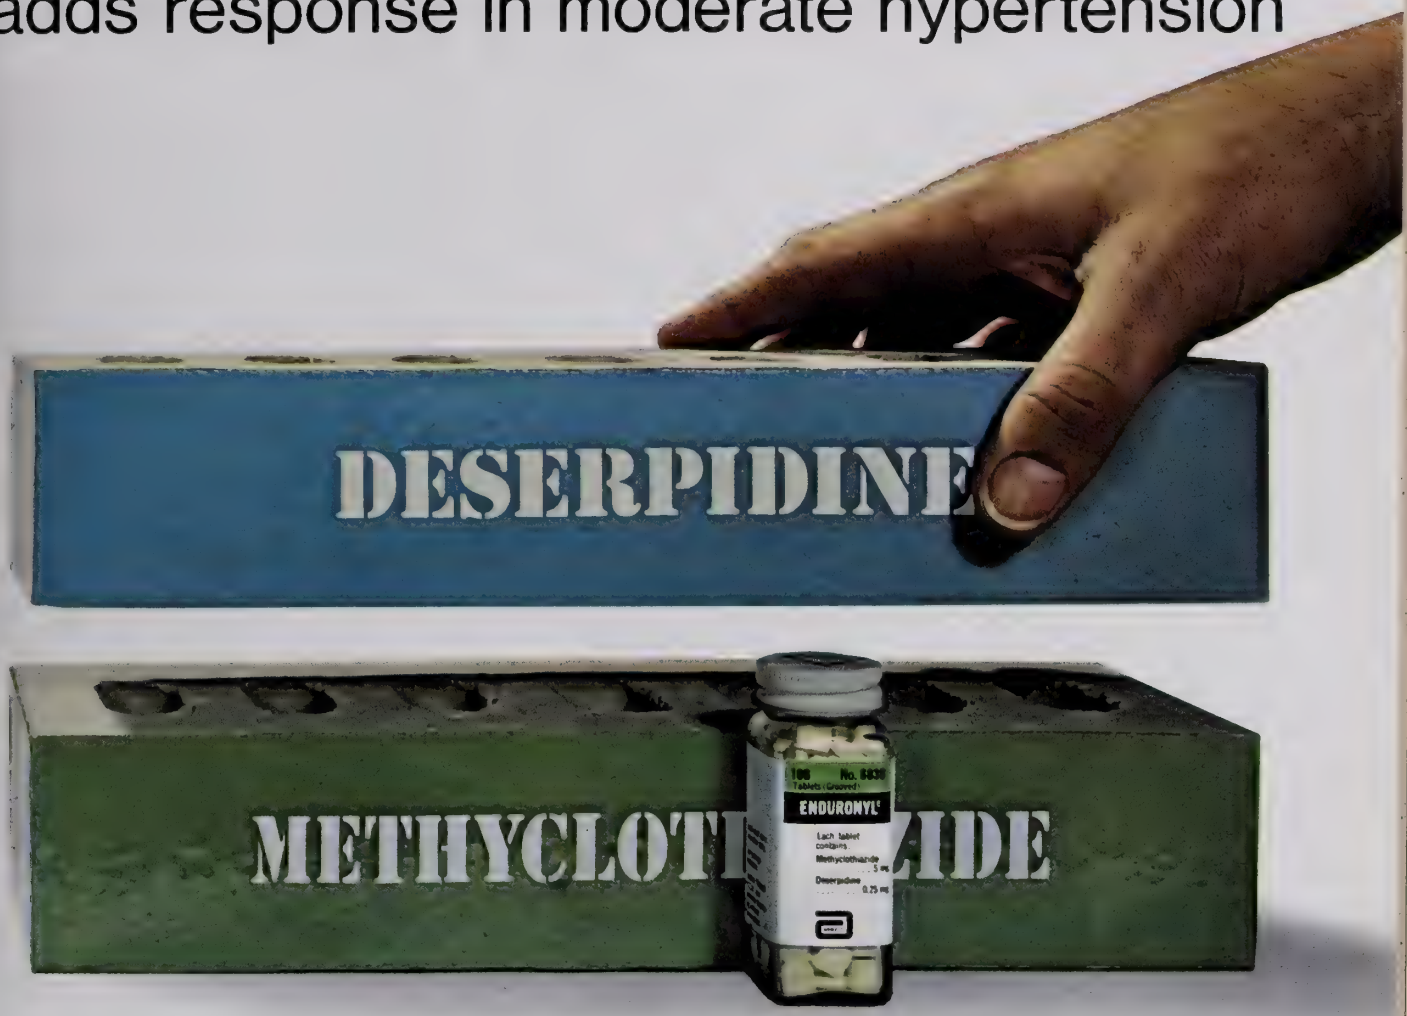
Of course, as with all thiazides, supplemental dietary potassium should also be considered.



Use Enduron as a basic therapy in patients with mild to moderate hypertension. A single 5-mg. tablet each day is ample in most cases.

Once a day, every day

ENDURON®



METHYCLOTHIAZIDE

MILD TO MODERATE TO SEVERE

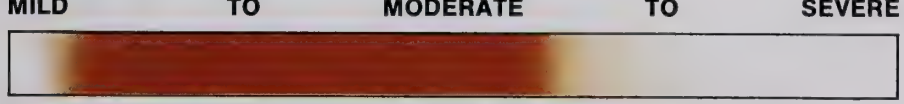
See Brief Summary on final page of advertisement

Enduronyl: Its deserpidine component adds response in moderate hypertension

Less frequent rauwolfia side effects than with reserpine

When you wish to build further response, consider shifting to Enduronyl.

Enduronyl adds a building block of *deserpidine*. This is a purified rauwolfia alkaloid available only from Abbott. It adds good antihypertensive and tranquilizing activity. Yet its incidence of untoward effects, particularly lethargy and depression, is lower than with reserpine.

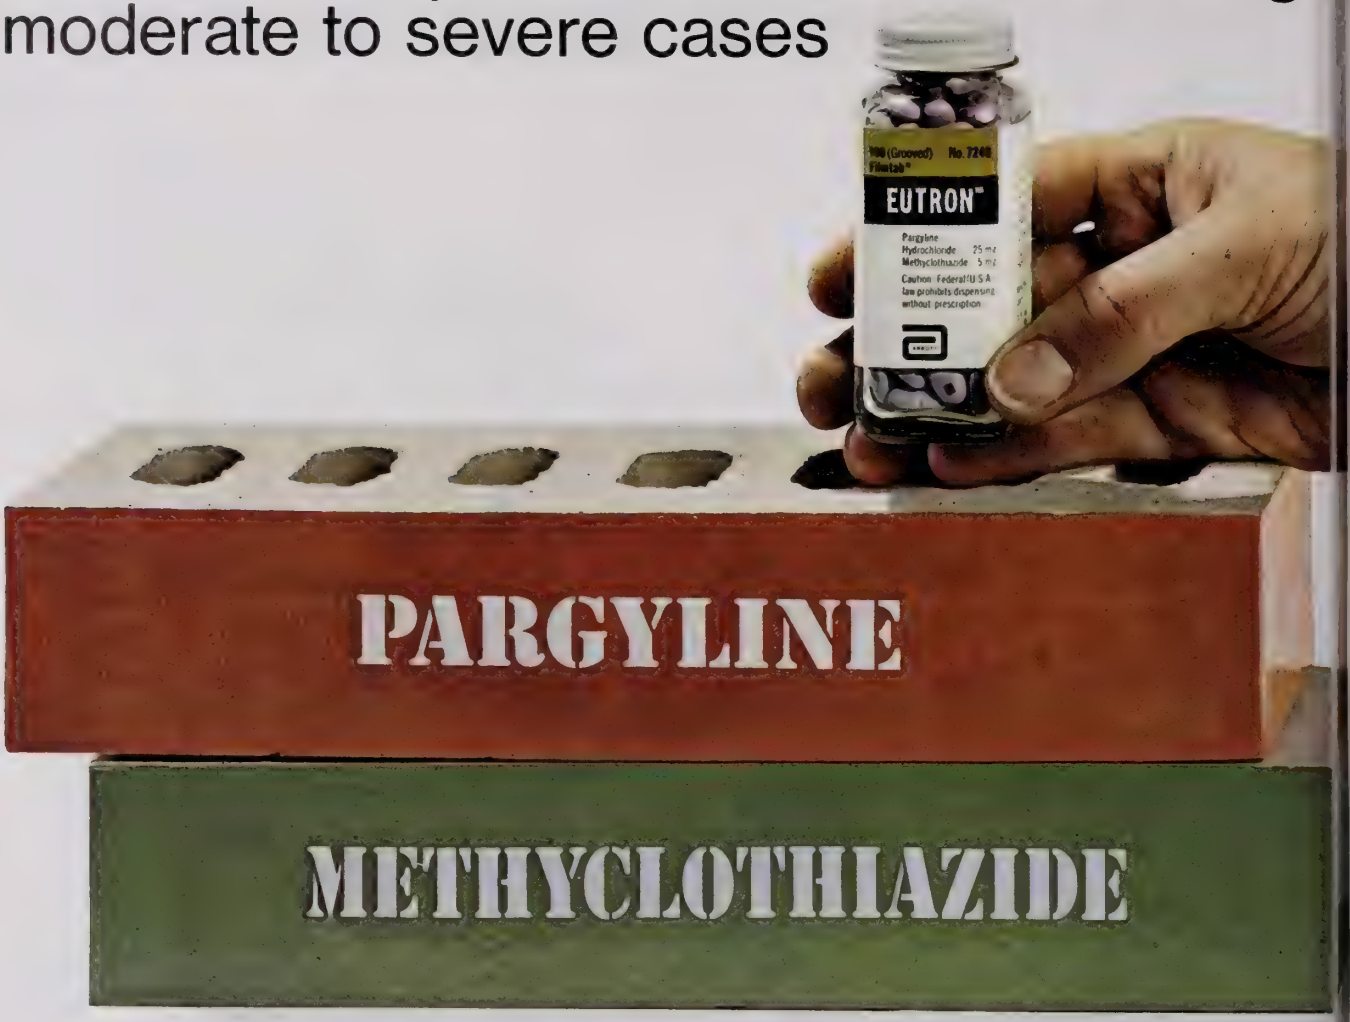


Enduronyl is available plain or Forte. The latter provides its variation where most helpful, by doubling the deserpidine.

Use Enduronyl for patients throughout the broad range of mild to moderately severe hypertension.

Once a day, every day

ENDURONYL®



METHYCLOTHIAZIDE 5 mg. with DESERPIDINE 0.25 mg. or (FORTE) 0.5 mg.

See Brief Summary on final page of advertisement

801094

Eutron: A unique combination for handling moderate to severe cases

Affords almost uniform diastolic reduction in all body positions

Eutron lowers diastolic pressures nearly equally, whether your patient is standing up or lying down.

Thus, in clinical trials, average *standing* diastolic readings were reduced from 112 pre-treatment to 90 post-treatment; *sitting* from 115 to 95; and *recumbent* from 112 to 94.

Note that following Eutron, the diastolic reductions were nearly alike in all three body positions.

Use Eutron for managing your moderate to severe cases. Its building blocks enhance each other; hence lesser doses often suffice.

Once a day, every day

EUTRON™

PARGYLINE HYDROCHLORIDE 25 mg.
with METHYCLOTHIAZIDE 5 mg.

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

ENDURON® | ENDURONYL®

METHYCLOTHIAZIDE

Each tablet contains Methyclothiazide 5 mg. with Deserpidine 0.25 mg. or 0.5 mg.

Indications: Edema and mild to moderate hypertension (Enduron), and mild to moderately severe hypertension (Enduronyl). More potent agents, if added, can be given at reduced dosage.

Contraindications: Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease or impending hepatic coma (hepatic coma due to hypokalemia has been reported in patients on thiazides). Do not use Enduronyl in severe mental depression, suicidal tendencies, active peptic ulcer, or ulcerative colitis.

Warnings: Consider possible sensitivity where there is history of allergy or asthma. If added potassium is indicated, dietary supplementation is recommended. Reserve enteric-coated potassium tablets for cautious use only when necessary, as they may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation often requiring surgery; discontinue them immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occurs. Neither Enduron nor Enduronyl contains added potassium.

Precautions: Use thiazides cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery, thiazides may reduce response to vasopressors, and increase response to tubocurarine. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia) in all patients. In hypokalemia (especially in digitalized patients) give supplemental potassium. In hypochloremic alkalosis, give supplemental chloride.

Use rauwolfias with caution in patients with history of peptic ulcer. Rauwolfias with anesthetics may produce hypotension and bradycardia. Discontinue Enduronyl two weeks before elective surgery. Consider vagal blocking agents during emergency surgery. In epilepsy, adjust anticonvulsant dosage. In electroshock, shorten stimulus strength and duration. In occasional patients with depressive tendencies, rauwolfias may precipitate severe mental depression that usually disappears when drug is stopped.

Adverse Reactions: Thiazide reaction include blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, serum uric acid or blood sugar; anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, symtomatic gout, and pancreatitis. Cutaneous vasculitis in the elderly has been reported with other thiazides. Adverse effects with deserpidine are qualitatively similar to those with reserpine, but their incidence is lower. These include nasal stuffiness, abdominal cramps or diarrhea, nausea, headache, weight gain, reduced libido and potency, peptic ulcer aggravation, epistaxis, skin eruption, asthma in susceptible patients, electrolyte imbalance, excessive salivation, and a reversible Parkinson's syndrome. Excessive drowsiness, fatigue, weakness, and nightmares may signal mental depression. Thrombocytopenia, purpura, and a symptom manifested by dull sensorium, deafness, uveitis, glaucoma, and optic atrophy are rare allergic reactions to other rauwolfias. Hypotension from antihypertensive agents may precipitate angina attacks in susceptible individuals. Usually adverse reactions disappear when drug is withdrawn.

EUTRON™

Each tablet contains Pargyline Hydrochloride 25 mg. with Methyclothiazide 5 mg.

Indications—Moderate to severe hypertension.

Contraindications—Pheochromocytoma, paranoid schizophrenia, hyperthyroidism and advanced renal failure. Not recommended in malignant hypertension, children under 12, pregnant patients.

Do not use with: centrally or peripherally acting sympathomimetic drugs; foods high in tyramine (e.g., aged and natural cheeses); parenteral reserpine or guanethidine; imipramine, amitriptyline, desipramine, nortriptyline or their analogues; other monoamine oxidase inhibitors; methyldopa or dopamine; separate Eutron and these agents by two weeks.

Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease; impending hepatic coma from thiazide-induced hypokalemia.

Warnings—Patients: 1. No other drugs (particularly "cold preparations" and antihistamines), cheese or alcohol without physician's consent. 2. Promptly report orthostatic symptoms, severe headache, other unusual symptoms. 3. Angina pectoris or coronary artery disease patients must not increase physical activity with improved anginal symptoms or well-being.

Physicians: 1. Use antihistamines, hypnotics, sedatives, tranquilizers and narcotics (meperidine contraindicated) cautiously in reduced doses. 2. Stop Eutron two or more weeks before elective surgery; in emergency surgery reduce premedication (narcotics, sedatives, analgesics, etc.) to 1/4 to 1/5; carefully adjust anesthetic dosage to patient response. 3. Use cautiously in advanced renal failure. 4. Pargyline may induce hypoglycemia. 5. Consider possible sensitivity reactions when a history of allergy or asthma is present. 6. If potassium is indicated, dietary supplement is recommended; enteric-coated potassium tablets may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation frequently requiring surgery; discontinue medication immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occurs; Eutron does not contain added potassium. 7. Possible systemic lupus erythematosus has been reported for thiazides.

Precautions—Pargyline: Use cautiously at reduced dosage: caffeine, alcohol, antihistamines, barbiturates, chloral hydrate, other hypnotics, sedatives, tranquilizers, narcotics. Periodically do urinalyses, blood counts, liver function tests, etc. Use with caution in liver disease. Watch for orthostatic hypotension, especially in impaired circulation (e.g., angina pectoris, coronary artery disease, cerebral arteriosclerosis); also, augmented hypotension in concomitant febrile illnesses. Reduce or discontinue if hypotension is severe. In impaired renal function watch for cumulative drug effects, elevated BUN and other evidence of progressive renal failure; withdraw drug if these persist. In surgery increased central depressant response (hypotension and increased sedative effect) can be controlled by (1) discontinuing at least two weeks prior; (2) in emergency surgery lowering dose of premedication; (3) when necessary, administering a vasopressor. Do not use in hyperactive and hyperexcitable patients. Pargyline may unmask severe psychotic symptoms where emotional problems pre-exist. Use cautiously in Parkinsonism, especially with antiparkinsonian agents. In prolonged therapy, examine for change in color perception, visual fields, fundi and visual acuity. Also, prolonged therapy has made certain patients refractory to nerve blocking effects of local anesthetics.

Methyclothiazide: Use cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery thiazide may reduce vasopressor response and increase tubocurarine response. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia). Give supplemental chloride if hypochloremic alkalosis occurs and supplemental potassium if hypokalemia occurs (especially in digitalized patients). Thiazides may decrease serum P.B.I. without signs of thyroid disturbance.

Adverse Reactions — Pargyline: Orthostatic hypotension and associated symptoms, mild constipation, fluid retention, edema, dry mouth, sweating, increased appetite, arthralgia, nausea, vomiting, headache, insomnia, difficult in micturition, nightmares, impotence, delayed ejaculation, rash, purpura, weight gain, hyperexcitability, increased neuromuscular activity and other extrapyramidal symptoms. Drug fever is extremely rare. Reduction in blood sugar and hypoglycemic effects are possible. Congestive heart failure has been reported in a few patients with reduced cardiac reserve.

Methyclothiazide: Blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, blood sugar or serum uric acid (gout may be induced); anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice and pancreatitis. Cutaneous vasculitis in elderly patients has been reported with other thiazides.

If side effects are severe or persist, reduce dosage or withdraw drug. 804438R

Dermatology

Swimmer's Itch and Seabather's Eruption

SWIMMER'S ITCH and seabather's eruption, although occurring in different geographical locations, often show similar clinical features. Swimmer's itch is acquired during the summer months by persons swimming or wading in certain lakes of Minnesota, Wisconsin and Michigan. Although seabather's eruption is most common along the Gulf and Atlantic Coasts of Florida from March to September, the patient may present himself to a northern physician on returning from travel. Both eruptions may puzzle those unfamiliar with the clinical picture of each disease.

Swimmer's itch (cutaneous schistosomiasis) is caused by a parasite, the definitive host most often being wild ducks and small rodents. The eggs from the adult schistosome are passed in the excreta of the host and infect the

Figure

fresh water snail, which serves as the intermediate host. When the water temperature rises, the snail releases the cercariae which then come in contact with and invade the swimmer's skin. The clinical picture and symptomatology depend on the person's previous exposures, the initial exposure producing only minor symptoms. Seven to ten days after swimming in infested water, erythematous papules develop on areas that have been submerged. However, areas covered by bathing suits are spared. In about two weeks the cercariae are cast off. With each subsequent exposure, the symptomatology is accelerated and intensified. An initial mild itching sensation lasting for a few minutes to an hour is followed in 10 to 12 hours by discrete, very pruritic papules which may become urticarial or even vesicular (Figure). Generalized urticaria, including unexposed areas, may occur in highly sensitized individuals. The eruption subsides after a few days.

Treatment, which is symptomatic, includes systemic antihistamines and soothing shake lotions. In severe and widespread eruptions, systemic steroids may be used. Preventive measures include thorough washing, preferably with a rough washcloth or towel or with a brush, and vigorous drying as soon as possible after exposure.

The cause of seabather's eruption is unknown. Schistosomes, jellyfish, men-of-war, algae and seaweed have all been mentioned as possible etiologic agents, but none has been documented. Within a few hours after the person leaves the water, erythematous pruritic papules and wheals develop on covered parts of the body; this is in contrast to swimmer's itch where covered areas are spared. The eruption progresses to crusted and vesicular papules resembling insect bites. Systemic symptoms such as chills and fever may be experienced. The lesions spontaneously disappear in seven to 10 days.

Treatment consists of oral antihistamines, corticosteroids, and soothing lotions and creams. Prophylaxis includes avoiding infested water and drying vigorously after leaving the water.

Shakespeare: Pharmacologia

Hebenon*

"Sleeping within my orchard,
My custom always in the afternoon,
Upon my secure hour thy uncle stole,
With juice of cursed hebenon in a vial,
And in the porches of my ear did pour
The leperous distilment; whose effect
Holds such an enmity with blood of man,
That swift as quicksilver it courses through
The natural gates and alleys of the body;
And with a sudden vigour it doth posset
And curd, like eager droppings into milk,
The thin and wholesome blood: so did it mine;
And a most instant tetter* barked about,
Most lazar-like,* with vile and loathsome crust,
All my smooth body."**

Grand Rounds

Viral Myocarditis

ERIK E. CARLSON, M.D.
Medical Resident

THE TERM myocarditis was first used in 1837 by Sobernheim[1] to denote inflammation of the myocardium. As used today, however, it refers to the myocardial lesions and clinical picture associated with a variety of infectious diseases, toxins and immune responses, as well as to myocardial inflammatory changes of obscure origin.[2]

Saphir,[3] in a series of 5,626 consecutive autopsies on adults, encountered 240 cases of myocarditis, 186 of which were non-rheumatic. Table 1 is a review of 1,402 cases of myocarditis by Gore and Saphir.[2] These cases, verified at autopsy between 1942 and 1946 at The Armed Forces Institute of Pathology, suggest that a wide variety of etiologic agents and diseases are active in the production of myocarditis. Of these, 70 (5%) are viral in origin. Other authors[4] suggest the incidence of general myocarditis to be as high as 7 to 10% of autopsies done on patients dying of infectious disease. The incidence increases with the number of blocks of tissue removed from each heart for microscopic examination[6] with the thoroughness of the pathologic examination.

Myocarditis

In a clinicopathologic study of thirty-three fatal cases of Asian influenza, Oseasohn et al. found typical microscopic changes in 14 of 33 cases.[5] Walsh et al.[6] found that four of 34 patients with Asian strain influenza developed serious cardiovascular symptoms. Silber[7] reports a series of 21 cases of myocarditis and two of pericarditis, six of which were associated with significant rises in antibody titers for influenza A and B in the period 1950-1956. Finland et al.[8] report two cases of non-bacterial myocarditis in which influenza A virus was isolated from the lungs.

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, February 6, 1968.

In Acute Anterior Poliomyelitis

Teloh[9] reviewed 47 fatal cases of acute anterior poliomyelitis autopsied between 1942 and 1951 and found 26 (55%) of 47 showed an acute myocarditis by microscopic examination of routine histologic sections. Further, during the year 1949 the incidence of myocarditis was 100% of all autopsied cases, suggesting the presence of a viscerotrophic strain of virus with a predeliction for the myocardium. Weinstein,[10] in a review of cardiovascular changes occurring in poliomyelitis, suggested the changes might be due either to direct viral invasion or indirectly via secondary effects on the nervous system, with persistent hypertension, shock, or prolonged anoxia secondary to respiratory insufficiency.

In Mumps

Roberts and Fox[11] report a case of mumps with death from congestive heart failure eight months after the clinical infection. Necropsy showed hypertrophy and interstitial myocardial fibrosis, leaving little doubt as to the pre-

TABLE I

Diseases Associated with Myocarditis* (From Gore and Saphir, 1948)

	1	2		1	2
Rickettsial diseases			Septicemia		
Scrub typhus	227	227	Streptococcus	11	23
Epidemic typhus	23	48	Staphylococcus	34	107
Rocky Mountain spotted fever	9	19	Pneumococcus	9	18
Diphtheria	144	221	Other acute bacteremias	15	Unknown
Subacute bacterial endocarditis	208	208	Acute glomerulonephritis	14	160
Rheumatic heart disease	130	130	Acute tonsillitis	12	Unknown
Meningococcemia	111	256	Acute nasopharyngitis	41	Unknown
Scarlet fever	24	44	Cellulitis, lymphangitis, and wound infections	13	Unknown
Weil's disease	7	8			
Relapsing fever	6	11	Tularemia	1	16
Syphilis (gummatous)	2	66	Brucellosis	2	4
			Miscellaneous (postinfectious)	13	Unknown
Chagas' disease	1	1			
Schistosomiasis	5	41	Exfoliative dermatitis	7	44
Malaria	5	135	Arsenical reaction	1	18
Trichinosis	2	2	Sulfonamide hypersensitivity	105	Unknown
Acute encephalitis	13	144	Disease unknown (so-called "idiopathic")	43	
Poliomyelitis	13	94			
Infectious mononucleosis	6	9	Starvation	33	50
Measles					
Guillain-Barre syndrome	3	30			
Mumps	1	8	Heat stroke		
Epidemic hepatitis	1	400	Surviving less than 24 hours	16	45
Smallpox	1	9	Surviving more than 24 hours	13	26
Virus pneumonia	32	222	Carbon monoxide poisoning (limited to patients who survived for an appreciable interval after the lethal exposure)	1	30
Tuberculosis	9	581	Emetine	1	70
Boeck's sarcoid	3	12	Burns	11	45
Coccidioidomycosis	11	48			
Blastomycosis	2	5	Total	1402	
Actinomycosis	1	9			
Torulosis	1	6			

*The figures in the first column represent the number of times myocarditis was encountered. Whenever possible the number of cases of each disease, screened to ascertain the first figure, is given in column 2. The ratio of the two thus provides a crude index of the frequency of myocarditis in each disease.

**Amer Heart J 34:827, 1947.

sence of preceding myocarditis. Other observers[12] report a 5 to 7% incidence of electrocardiographic changes in patients during mump epidemics. Atrioventricular dissociation associated with Stokes-Adams syndrome, presumably secondary to mumps myocarditis, was satisfactorily treated with a transvenous pacemaker by Nolan and Thompson.[13]

In Other Diseases

Garrison and Swisher[14] used adrenocorticotropic hormone in the treatment of intractable heart failure in a myocarditis of unknown etiology with good clinical result. Viral studies were not done.

Hall and Finegold[15] found transient electrocardiogram abnormalities with ST-T wave changes, ectopic beats and conductive delay in six of 20 patients *with Reiter's syndrome.*

Friedburg[16] suggests that a *post-infection myocarditis* may result from a hypersensitivity reaction in which a virus, or other agent, "by altering the antigenic properties of the heart or by acting in conjunction with anti-heart antibodies" could produce an auto-immune reaction.

Kline et al.[17] report two patients with *endocardial fibroelastosis* and discuss related research in dogs. They offer evidence that endocardial fibroelastosis is related to chronic myocarditis and secondary cardiac lymphatic obstruction or to chronic lymphatic obstruction of any other etiology.

McNally and Qamer[18] report a case of *generalized vaccinia* which developed a loud pericardial friction rub and ST-T changes of an acute pericarditis. This was rapidly resolved with the administration of vaccinia immune globulin.

As previously noted,[2] other viral infections including *infectious mononucleosis, encephalitis, and hepatitis* have also been implicated in the production of a myocarditis.

The spectrum, then, of myocardial disease secondary to viral infections is broad and highly variable. Nevertheless, most observers will agree on the basic production of a myocarditis whether it is in origin, infectious, toxic or auto-immune, following a virus infection.

Pathology

Gross examination of the heart reveals nonspecific "toxic" changes with a flabby, yellowish to pallid myocardium and biventricular dilation. Mural thrombi may be present. Not infrequently, however, the heart may appear relatively normal to gross examination.

Cut surfaces may reveal subepicardial and subendocardial petechiae and hemorrhagic extravasation, as was reported in six cases by Oseasohn et al.[5]

Microscopic

Histologically the lesions include focal or diffuse invasion of the interstitial tissue with lymphocytes and monocytes and less commonly polymorphonuclear cells. A variable degree of interstitial edema may be present. Plasma cells and necrosis of muscle fibers are not prominent. If the infiltration is sparse and focal, the cellular reaction may be perivascular with a relatively normal adjacent myocardium.[4-5]

One observer reports four patients in whom the myocardial arteriols showed fibrinoid degeneration with focal fibrin mural thrombi in the involved vessels.[5]

Clinical Diagnosis

The clinical diagnosis of a viral myocarditis is frequently one of inference or association of non-specific cardiac signs in the presence of a suspected viral disease.

Signs[19]

Sinus tachycardia (rarely bradycardia)
Abnormal rhythms, including gallop rhythm
Enlargement of the heart
Faint or snapping quality of the first heart sound
Cardiac insufficiency
Defective intraventricular or atrioventricular conduction and abnormal final ventricular deflections (S-T and T)
Increased serum glutamic oxaloacetic transaminase
Constitutional and special manifestations of the basic infection (fever, leukocytosis, increased sedimentation rate, increased C-reactive protein, positive blood culture)

The clinical features of 33 fatal cases of Asian influenza[5] are summarized in Table 2. Other observers[4,6,7,20] support the variable symptomatology and occasionally fulminating course with rapid progression to death that these cases represent. Not infrequently, this may be due to the acute myocarditis, with consequent heart failure, arrhythmias and cardiac arrest being the terminal event.

Abelman[20], in an excellent general review of myocarditis, suggests that frequently myocarditis is not recognized clinically, even in the presence of signs of cardiac involvement, because these signs are frequently overshadowed by the manifestations of the primary, systemic disease.

Abelman further suggests that sub-clinical myocarditis may be a common accomplice of viral infections in view of the frequently focal nature of the pathologic findings at autopsy. Consequently, unless such focal lesions produced major derangements of conduction, or arrythmias, the large organ reserve the heart possesses would allow relatively normal cardiac function to continue. The addition, however, of a pre-existing cardiovascular stress, such as anemia, fever, alcoholism, hypervolemia, hyperthyroidism, work and pregnancy may lead to rapid decompensation and cardiac failure.[20]

Electrocardiogram

Electrocardiographic changes in viral myocarditis cover a wide spectrum of abnormalities (Tables 3, 4). Disturbances of rhythm are common. Silber[7] found first-and second-degree A-V block and bigeminy (due to ventricular premature systoles) to predominate in his series of 23 patients. Other arrythmias included atrial ectopic beats, nodal tachycardia and any form of sinus arrythmias. Sinus bradycardia has been reported,[6] as has third-degree A-V block.[13]

Changes of contour including non-specific ST-T changes, left heart strain, ischemia, pericarditis, and wandering pacemaker have been reported.[4,6,7,21]

Vectorcardiograms were done in 20 patients by Walsh et al.[6] who found that in 16 of 20 patients the afferent limbs of QRS loops were distorted. At the peak of illness, four patients demonstrated arching similar to that ob-

served in diaphragmatic myocardial infarction. These changes resolved with convalescence.

Therapy

Although it is not possible to treat viral myocarditis specifically, many diseases causing an acute myocarditis *are* treatable and should be carefully

TABLE 2*
Clinical Features of 33 Fatal Cases of Asian Influenza

Case No.	Age	Sex	Race	Date of Death	Clinical Data
2	22	M	N	10/1	Sudden onset of influenza-like illness; patient admitted to hospital with signs of bilateral pneumonitis; died despite cardiac-resuscitation attempt.
6	10	M	N	10/10	Sudden onset of influenza-like illness with epistaxis; 7 siblings of patient simultaneously ill.
12	21	M	W	10/17	Patient returned home from work because of influenza-like illness; found dead in bed that night.
14	47	F	W	10/17	Sudden onset of influenza-like illness; bilateral pneumonitis developed; chronic rheumatic mitral stenosis, uncomplicated heart failure.
15	48	M	N	10/19	Patient sent home from work because of influenza-like illness; found dead in bed that night.
16	77	M	W	10/20	Sudden onset of influenza-like illness, with increasing congestive heart failure; arteriosclerotic heart disease with remote healed infarct; adenocarcinoma of colon.
20	31	F	W	10/25	Patient found dead on floor of home on day after complete dental extraction under inhalation anesthesia.
27	9	M	W	11/5	Mild coryza, followed on third day by convulsions, extensor spasm, fever and coma; patient died one hr. after onset of seizure (known to have epilepsy).
31	17	M	W	11/18	Onset of "cold"; rapid development of dyspnea, tachypnea, cyanosis & signs of bilateral pneumonitis.
3**	32	F	N	10/4	Influenza-like illness for four days; patient admitted to hospital on fourth day in extremis with signs of bilateral pneumonitis and meningismus.
4	24	F	N	10/7	Sudden onset of influenza-like illness, followed by pneumonitis, in fifth month of pregnancy; chronic rheumatic mitral stenosis uncomplicated by heart failure; patient died despite steroid therapy.
5	17	F	N	10/8	Sudden onset of influenza-like illness, with signs of bilateral pneumonitis; patient died despite steroid therapy.
8	44	F	W	10/13	Influenza-like illness for one wk.; patient found dead in bed (chronic alcoholism with liver cirrhosis).
9†	51	M	W	10/13	Vague influenza-like illness for one wk.; patient continued to work; found dead at home.
7†	23	F	N	10/13	Patient six months pregnant; sudden onset of influenza-like illness with spontaneous abortion on third day; sudden collapse on sixth day; died despite steroids and cardiac-resuscitation attempt.
10†	13	M	W	10/15	Influenza-like illness followed by seizures, coma and fever; lumbar puncture negative.
11	16	M	W	10/16	Sudden onset of influenza-like illness, signs of bilateral pneumonitis on third day; patient found dead in bed on fourth day.
13	73	M	W	10/17	Patient, aged widower living alone, sick for five days; no other history; found dead in bed.
18	9/12	F	N	10/22	Coryza followed by vomiting & diarrhea; patient found dead in bed.

†Virus-negative cases.

ruled out in the workup. Every effort should be made to identify the specific organism involved.

The presence of heart failure suggests the usual supportive measures, including bed rest, salt restriction, diuretics, O_2, cardiac glycosides and phlebotomy as indicated.

Bed Rest

Bed rest, in the presence of a myocarditis, is specific and important therapy. Experimental studies with mice[22,33] show that strenuous activity in the form of forced swimming in mice infected with coxsackie A9 virus, strain 13, lead to both cardiomegaly and enhanced viral replication. Similarly, mice infected with the parasite trypanosoma cruzi, when forced to exercise, also showed an increase in cardiac to body weight ratios and increased numbers of parasites.

Digitalis

The presence of increased myocardial irritability suggests that when used, digitalis should be given (1) in submaximal amounts, (2) as the shorter

acting preparations, and (3) with frequent monitoring of the electrocardiogram.

Control Arrythmia

Arrythmias should be controlled where possible with agents such as xylocaine, procaine amide, quinidine, or dilantin.

Complete A-V block is, as always, an indication for electrical pacing if unresponsive to atropine and isuprel.

Steroids are controversial. Experimentally they seem to enhance viral replication[24] and reduce intrinsic host resistance in mice.[25] However, in the hands of clinicians, steroids appear to have been lifesaving in the treatment of viral myocarditis with intractable heart failure. Ainger[26] reports a series of eight children treated for periods varying from 42 to 145 days, with uniformly good responses.

Case Report

History of Present Illness

This was the first Hennepin County General Hospital admission for this 44-year-old negro male. The patient gave a history of two weeks of progressive ankle swelling, shortness of breath, orthopnea, paroxysmal nocturnal dyspnea, and a weight loss of approximately 20 pounds over the previous past two and one-half months. He had a medical history of drinking three pints of hard liquor, three to four pints of wine, and one-half case of beer per week. His medical history also revealed treatment for gonococcal infections eleven times with penicillin, and treatment for syphilis in 1943 with heat therapy.

Physical Examination on Admission

The blood pressure was 120/90, the apical rate 130 per minute and irregular. The chest showed fine moist diffuse rales at the bases and to the level of the scapulae bilaterally. No murmur was noted, but there was a protodiastolic gallop present. The point of maximum impulse was prominent in the anterior axillary line. The liver was not palpable but was percussable four fingerbreadths below the right costal margin and not tender. The spleen was not palpable. Extremities showed 4+ pitting edema to the knees. The remainder of the physical examination was unremarkable.

Hospital Course

On admission the patient's chest x-ray showed massive cardiomegaly with the cardiothoracic ratio approaching 70%. The pulmonary vasculature was prominent and there was an alveolar infiltrate consistent with a pulmonary edema. Venous pressure on admission was 22 cm. Circulation time was 75 seconds arm-to-tongue with a very sharp end point. Cardiac fluoroscopy showed a very quiet heart without evidence of calcification. A CO_2 infusion study of the heart was within normal limits. A radioactive iodine-tagged albumin scanogram of the heart was also found to be within normal limits. A paradoxical pulse was not present. The patient, however, continued to run a very narrow pulse pressure in the range of 20 mm. of mercury throughout his hospital stay. Laboratory data on admission showed a hemoglobin of 14.9 with a total white count of 3,600 cells. Differential showed 42 neutrophils, 52 lymphocytes and 6 eosinophils. Antistreptolysin O titer on admission was 50 Todd units. The sedimentation rate was 14. Lupus erythematosus tests were negative. Serum glutamic oxaloacetic transaminase on admission was 32, rising to a high of 85 units and sinking slowly back into the range of 20-30 units. Acute and convalescent sera for viral studies were sent to the State Boards and showed the following:

	Dec. 13	Dec. 26	Jan. 19
Hemagglutination-Inhibition Titer A_2.....	1/20	1/640	1/1280
Complement Fixation Adenovirus	1/8	1/8	1/8
Cold Agglutinins	1/64	1/128	1/128

Attempts at isolating the virus from the patient's sputum to date have been unsuccessful,

On admission the patient's weight was 206 pounds. He was put on a regimen of 500 mg. salt-restricted diet, treated vigorously with diuretics, digitalis and placed on strict bed rest. On this regimen his weight steadily decreased to 159½ pounds ten days after admission. Multiple electrocardiograms were done. In general, these tracings showed a sinus rhythm with left axis deviation, left ventricular hypertrophy, left ventricular strain, and a first-degree A-V block. The QRS complex was 0.10 seconds in duration and was thought by some to show an incomplete left bundle branch block. A vectorcardiogram on January 17, 1968, showed left ventricular hypertrophy. Chest x-rays on serial examination showed a slow decrease in the size of the heart over the period of hospitalization. On January 9, 1968, the circulation time had decreased to 45 seconds and the venous pressure was 11 cm. On January 23, 1968, the circulation time was down to 20 seconds with the venous pressure 9.8. The patient has continued to have intermittent gallop rhythm, and at the time of this summary still shows a cardiothoracic ratio of 60%.

Diagnosis

1. Acute viral myocarditis influenza Type A-2.
2. Chronic alcoholism.

References may be secured from the Grand Rounds Editor.

The Pickled Brain

None of our family on either side, so far as I can find out, had ever practiced medicine. My own experience of doctors had been a chequered one, but at my father's suggestion I gladly went up and discussed the matter with our country family doctor.

The only remaining memory of that visit was that the old doctor brought down from one of his shelves a large jar, out of which he produced a pickled human brain. I was thrilled with entirely new emotions. I had never thought of man's body as a machine. That this weird, white-puckered-up mass could be the producer or transmitter of all that made man, that it controlled our physical strength and growth, and our responses to life—why, it was absolutely marvelous.

My father saw at once on my return that I had found my real interest, and put before me two alternative plans, one to go to Oxford, where my brother had just entered, or to join him in London and take up work in the London Hospital and University, preparatory to going in for medicine. I choose the latter at once—a decision I have never regretted.*

*Wilfred T. Grenfell (1865-1940) in Why We Became Doctors, edited by Noah D. Fabricant, M.D., 1954.

Editor's Note: Wilfred Grenfell established the Labrador mission in Newfoundland, later extending his mission service to six hospitals, seven nursing stations, four hospital ships, four orphanges, fourteen industrial centers, three agricultural stations, and twelve clothing distribution centers. He was knighted by George V.

Sorrel cleanses the body of feculent humours—if the plant be eaten green or its juice drunk, it helps an offensive breath, fastens loose teeth, cures the putrefaction of the gums, and is extremely beneficial in all cases where the blood is too fluid and the vessels lax.—Boerhave

---

That man can interrogate as well as observe nature was a lesson slowly learned in his evolution.—Osler

Abstracts, Briefs and Commentaries

CARCINOMA OF THE PENIS IN A JEW CIRCUMCISED IN INFANCY

There are only four authenticated cases of carcinoma of the penis occurring in Jews circumcised at birth. Wolfarst reported a case in a non-circumcised Jew. Margolis records a case of a carcinoma of the penis in a Gentile circumcised at birth, not documented, however. Lecklider reported four cases in Hebrews, but the circumcision statuses are not known.

Ewing quoted Bessesen: "Carcinoma of the penis is unknown to the Jewish race. It is commoner in other races and obviously due to the irritation of decomposing smegma and infection."

Case Report

A Jewish male, 65 years of age, was ritually circumcised on the eighth day after birth. He is married but has no children. He has had no venereal disease.

For over 10 years he has had an irritating lesion at the base of the glans. During the last three years this has progressed to a warty growth which left a bleeding base when it flaked off. There was a papillary growth seen on examination, and an area of hyperkeratosis on the corona. No inguinal glands were palpable.

The growth and the hyperkeratotic area were excised. Histological examination revealed a squamous-celled carcinoma of unusually pronounced papillary structure. Radio therapy was given to the shaft and glans. There has been no recurrence after six years.

Summary

A case of carcinoma of the penis in a Jewish male circumcised at birth is presented. This is only the fifth case recorded.

GANGRENE OF THE HAND FOLLOWING INTRA-ARTERIAL INJECTION

Three patients had inadvertent injection of intravenous drugs into an artery of an upper extremity. Each resulted in gangrene of portions of the hand, resulting in later amputation. The drugs involved were amobarbital

sodium, meperidine HCl and promethazine mixture, and promazine HCl. Despite immediate local and general therapy, gangrene was not avoided. The clinical picture is characteristic: immediate pain in the arterial distribution and various reactions of the skin and pulses. Awareness of aberrant locations of the upper extremity arteries, poor lighting, failure to inject a small test dose, and not checking for pulses distally are probable factors to correct for prevention.

First London Pharmacopoeia

In 1618 the First London Pharmacopoeia appeared, now considered the outstanding event in pharmacopoeia making. It was not the initial pharmacopoeia, for in 1498 one had been issued in Florence, another in Barcelona in 1535, followed during the sixteenth century by John Jacob Wecker's "antidotary," the compilation of formulas by Valerius Cordus in Nuremberg, in 1546, and the Augsburg Pharmacopoeia in 1564. The thousands of formulae printed in these pharmacopoeias were those of the authorities of the past such as Galen, Avicenna, Rhazes and Nicholas Preapositus. The first London Pharmacopoeia, sponsored by the College of Physicians in London, recorded every known remedy of the ancients with great catholicity and also included many prescriptions attributed to contemporary authorities. It contained 1,028 simple drugs and 932 preparations. Many revolting substances are listed as well as medicines familiar today, such as potassium bitartrate, sulphur, potassium nitrate, calomel, lead acetate, antimony oxide, aloe, calcium hydroxide, scamony and squill.

That the popular use of bizarre medication continued is evidenced by the cures recommended by the standard reference works of the eighteenth century such as Zedler's Universal Lexicon and Chamber's Cyclopedia. The former declares that an ape's heart, roasted, dried and pulverized, strengthens the heart and dispels melancholy; that the ashes of a stork distilled into an essence is effective against poisons and the pest; that the brain of a dog of solid color, when cooked and eaten, dispels delirium caused by the bite of a mad dog; that the gall of a black suckling dog ground into a powder or mixed with vinegar is a cure for apoplexy, lethargies and vertigoes. In 1739, Joanna Stephens sold to Parliament for five thousand pounds her remedy for stone, which was endorsed by Cheselden, Sharp and Hawkins. Upon analysis, it proved to be a "mixture of egg shells, garden snails, swine's creasses,* soap and such vegetable ingredients as burdock seeds,* hips and haws.**

Sorrel

Sorrel sharpens the appetite, assuages heat, cools the liver, and strengthens the heart; it is an anti-scorbutic, resisting putrefaction, and in the making of sallets imparts a grateful quickness to the rest as supplying the want of oranges and lemons.—John Evelyn

Book Reviews

Books, the children of the brain.—Swift

CLINICAL HEMATOLOGY—Maxwell M. Wintrobe, M.D.: New 6th edition. Pages XXV plus 1287. Total illustrations 278. In color 76 on 21 plates. Price: $22.50. Lea and Febiger, Philadelphia 1967.

Dr. Wintrobe has rewritten better than 50 per cent of the text. He has added many new black and white figures and some new tables, and he has revised others. Electron photomicrographs are presented of ribosomes, a basophilic erythroblast, a reticulocyte, an expelled erythroblast nucleus, and a myeloblast. Additional electron photomicrographs of megakaryoblasts, lymphoblasts, monoblasts, myeloma cells, plasma cells, and megaloblasts would have enhanced the value of the book for students. The photomicrographs of cells in Plates III, V, XV, and XVIII lack morphologic sharpness and color differentiation. Plates IV, VI, VII, IX, XIII, XIX, and XXI show color drawings of cells that represent an artist's concept rather than the actual microscopic appearance.

The chapter "The origin and development of the cells of the blood in the embryo, infant and adult" has been extensively revised, and the section "Cytology and molecular aspects of cell growth and development" is new.

The methods of Berman and Axelrod, and those of the reviewer are combined into one procedure for the preparation of sections from aspirated material (page 31). The method as described needs revision. The thickness of the outer lamina of the sternum is given as 0.2 to 5 mm. and for the depth of the cavity 5 to 15 mm. (page 30). These measurements differ from those recorded by this reviewer of 0.8 to 1.5 mm. for the lamina and 6 to 9 mm. for the cavity (Minnesota Med 49:1321, 1966). Correctness of such data is important to the inexperienced operator, because he can easily push the needle through the entire bone, particularly when it is osteoporotic.

In the chapter "Principles of technic of blood examination" the directions read: "If the stain is an aqueous one and preliminary fixation is necessary, this may be accomplished by heating the slides at 120° to 125° C. for a few minutes; or passing them through a small flame 3 or 4 times." Procedures such as these produce undesirable cellular and staining artefacts.

Dr. Wintrobe has brought up to date "Pernicious anemia and related macrocytic anemias." To this chapter he appends "Hereditary orotic aciduria," a condition which may produce megaloblastosis refractory to vitamin B_{12} therapy but responding to uridine.

The chapter "Paraproteinemias" is new. Color photomicrographs of myeloma cells and lymphoid cells, the latter characteristic of Waldenström's macroglobulinemia, are shown in Plate XX.

For students to appreciate the morphology of Sternberg or Reed-Sternberg cells, color or black and white photomicrographs should have accompanied the chapter "Conditions chiefly affecting lymph nodes and the spleen." Dr. Wintrobe states in the section "Infectious mononucleosis:" "In spite of the failure to identify the agent most investigators now believe that infectious mononucleosis is caused by a virus, but this must be one which is very delicate, easily destroyed and transmitted only with difficulty, possibly by intimate contact." Recent research on the Epstein-Barr virus by J. C. Niederman et al. (JAMA 203:205, 1968) suggesting an etiologic role for this virus in this disease unfortunately was published too late to be cited in the book. The article, however, by Dr. A. C. P. Campbell (J Path Bact 60:629, 1948), the first investigator describing reticulum hyperplasia, proliferation of pleomorphic lymphoid cells, and presence of granuloma-like structures in the marrow of patients with Pfeiffer's glandular fever (infectious mononucleosis), should have been cited in the bibliography.

E. M. Schleicher, Ph.D.
Minneapolis, Minnesota

HANDBOOK OF FRACTURES—By Ralston. Publication date: November, 1967. Price: $10.75. C. V. Mosby Company, 299 pages, 156 illustrations.

This small but compact text should appeal to the medical student and intern for it is very readable, amply illustrated, and not verbose. The author has done an admirable job of presenting the major points and principles of treatment of the commonly seen fractures.

It is noteworthy, also, that the author has included in each section a lucid review of the relevant anatomy and physiology in order that the reader might be better prepared to render effective treatment.

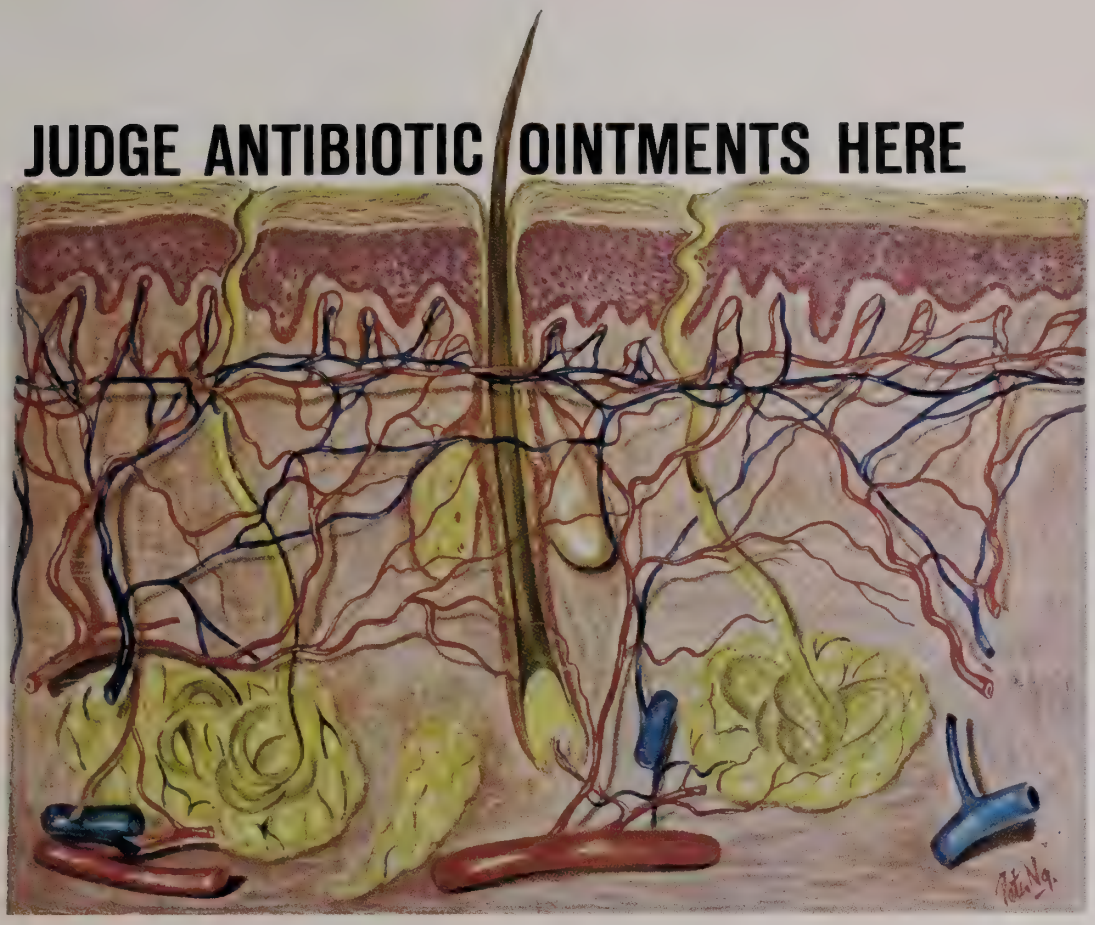
Harrison H. Farley, M.D.
Minneapolis, Minnesota

SAN FRAN CISCO AMA '68

The excitement of San Francisco's famous sites is waiting for you. Chinatown, the Golden Gate Bridge, Fisherman's Wharf, Telegraph Hill, will add to five memorable and stimulating convention days. Plan to attend now and look forward to an excellent convention in a city of unlimited charm.

Continue your postgraduate education with a varied program of • four General Scientific Meetings on Auto Accidents, Health Care Planning, Infectious Diseases, Treatment of Advanced Malignant Disease • 23 Section Programs • Color Television • Medical Motion Pictures • and over 600 scientific and industrial exhibits. All are designed to bring you up-to-date on what is making medical news today. You will attend lectures by the nation's outstanding medical authorities and discuss with them the significant advances in medicine.

In addition the AMA TV network will present more than 40 hours of convention news.



Reserve now for the Scientific Awards Dinner in honor of the Scientific Award Winners—Wednesday, June 19, 1968. Since space is limited, we suggest you make your reservations before June 3, 1968. Tickets are $10.00 each, payable in advance.

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA, May 6, 1968.

SAN FRANCISCO, CALIFORNIA · JUNE 16-20, 1968

AMERICAN MEDICAL ASSOCIATION'S 117th ANNUAL CONVENTION · BROOKS HALL

JUDGE ANTIBIOTIC OINTMENTS HERE

Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Complete literature available on request from Professional Services Dept. PML.

New

Therapeutic breakthrough in non-narcotic control of the pain of

Tegretol®
carbamazepine

trigeminal neuralgia

Warning
Fatal cases of aplastic anemia have been reported following treatment with Tegretol. Agranulocytosis, thrombocytopenia and transitory leukopenia have also been observed.
Complete blood and platelet counts should be done prior to and at regular intervals during treatment with the drug (see recommendations under "Important Note and Precautions") to help in the early detection of serious bone marrow injury. Abnormalities in initial blood tests should rule out use of the drug. Also, patients should be made aware of such early toxic signs of a potential hematologic problem as fever, sore throat, mouth ulcers, easy bruising and petechial or purpuric hemorrhage. Should such signs appear, the patient should be advised to discontinue the drug and to report to the physician immediately.

Indication Tegretol is indicated in the treatment of the pain associated with true trigeminal neuralgia. It is not a simple analgesic and should never be administered for relief of trivial facial aches or pains.
Contraindication Do not use in those with a known sensitivity to any tricyclic compound or in those being treated with M.A.O.I. agents. As long a period as possible should elapse before using Tegretol in patients who have been treated with M.A.O.I.'s, with a minimum of 7 days. In such cases, initial dosage should be low and the patient's reaction to gradual increments closely observed.
Important Note and Precautions Familiarity with the clinical symptoms which lead to an accurate diagnosis of true trigeminal neuralgia and with the complete prescribing information, careful patient selection, a thorough examination before treatment and close patient supervision throughout the treatment period are essential to the safe and effective use of this drug.
Where feasible, Tegretol should not be used in conjunction with any potent drug which may increase the possibility of toxic reactions.
In pregnancy, the drug should not be prescribed during the first trimester and thereafter only to patients in whom the clinical situation warrants the potential risk. It should not be administered to nursing mothers.
Patients with increased intraocular pressure should be closely observed during treatment with this drug because of its anticholinergic effect.
Because of the drug's relationship to other tricyclic compounds, the possibility of activation of latent psychosis and, in the elderly, of confusion or agitation, should be considered.
Dizziness and drowsiness may occur and patients should be cautioned about the hazards of operating machinery or automobiles and of engaging in other hazardous tasks.
Use cautiously in patients with a history of coronary artery disease, organic heart disease, congestive failure or liver disease.
Before initiating therapy, the following laboratory procedures should be performed:
1. Complete blood and platelet counts which, if abnormal, should rule out the use of the drug.
2. Baseline evaluations of liver function.

During treatment with Tegretol, the following laboratory procedures should be performed:
1. Complete blood and platelet counts should be done at intervals of one week during the first month of drug treatment, every two weeks during the second and third months, and at monthly intervals thereafter for as long as the patient is taking the drug. A trend toward a decreasing white blood cell count should suggest a dosage reduction and more frequent laboratory and clinical evaluations. Should this trend continue, the drug should be discontinued.
2. Liver function tests must be performed at regular intervals during treatment with this drug since liver damage may occur during therapy. The drug should be discontinued immediately in cases of aggravated liver dysfunction or active liver disease.
3. Periodic eye examinations, including slit-lamp, funduscopy and tonometry, are recommended for patients being treated with this drug since many phenothiazines and related drugs have been shown to cause eye changes.
4. Complete urinalysis and BUN should be done on patients treated with Tegretol because of observed renal dysfunction.

Adverse Reactions Dizziness, drowsiness, unsteadiness on the feet, nausea, vomiting, aplastic anemia, transitory leukopenia, agranulocytosis, eosinophilia, leukocytosis, thrombocytopenia, purpura, abnormalities in liver function tests, cholestatic and hepatocellular jaundice, urinary frequency, acute urinary retention, oliguria with elevated blood pressure, albuminuria, glycosuria, elevated BUN, microscopic deposits in the urine, impotence, disturbances of coordination, confusion, headache, fatigue, blurred vision, transient diplopia and oculomotor disturbances, speech disturbances, abnormal involuntary movements, peripheral neuritis and paresthesias, depression with agitation, talkativeness, nystagmus, tinnitus, paralysis and other symptoms of cerebral arterial insufficiency, pruritic and erythematous rashes, urticaria, Stevens-Johnson syndrome, photosensitivity reactions, alterations in skin pigmentation, exfoliative dermatitis, alopecia, diaphoresis, recurrence of thrombophlebitis, erythema multiforme and nodosum, aggravation of disseminated lupus erythematosus, gastric distress, abdominal pain, diarrhea, constipation, anorexia, dryness of the mouth and pharynx, glossitis, stomatitis, fever, chills, adenopathy, lymphadenopathy, aching joints and muscles, leg cramps, conjunctivitis, left ventricular failure, aggravation of hypertension, hypotension, syncope and collapse, edema, aggravation of coronary artery disease and congestive heart failure. (Whether these cardiovascular effects are drug-related is not known. However, some of these complications have resulted in fatalities.) The necessity for discontinuing the drug should be dictated by the gravity and severity of the adverse reactions.
Dosage and Administration The drug should always be taken with meals, if possible.
Initial: One-half tablet (100 mg.) b.i.d. on the first day. Thereafter, the dose should be increased in one-half tablet (100 mg.) increments every 12 hours until freedom from pain is achieved. To relieve pain, between 200 mg. and 1200 mg. per 24 hours may be necessary.
Maintenance: Initial control of pain can be maintained in most patients with a dose of 400 mg. to 800 mg. daily. Maintenance doses may range between 200 mg. and 1200 mg. daily.
At least once every 3 months during treatment period attempts should be made to discontinue the drug or to reduce the dose to the minimum effective level.
Availability Round, white, single-scored tablets of 200 mg. in bottles of 100 and 1000. (B)46-820-A

when you want to provide the combined benefits of two accepted agents in the treatment of mild to moderate hypertension. (Contraindications: history of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.)

when you want to prescribe therapy that is generally well tolerated.

(However, adverse reactions may occur. For a complete listing, please refer to the full prescribing information which is summarized below.)

when your patient wants an easy-to-remember and reasonably priced regimen. (One tablet a day usually costs about a dime.)

Indications: Hypertension. **Contraindications:** History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. **Warning:** With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue 1 week before electroshock therapy, and if depression or peptic ulcer occurs. **Use in pregnancy:** Regroton should be used in pregnant patients or in women of childbearing potential only when, in the judgment of a physician, its use is deemed essential to the welfare of the patients; adverse reactions (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential problems in the newborn. **Precautions:** Antihypertensive therapy with Regroton should always be initiated cautiously in post-sympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue Regroton therapy two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, Regroton should be discontinued and potassium supplements given, provided the patient does not have marked oliguria. Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients. **Adverse Reactions:** The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. **Average Dosage:** One tablet daily with breakfast. **Availability:** Pink, single-scored tablets in bottles of 100 and 1000. **For details, see complete Prescribing Information.** (B)46-600-B

General Hospital Must be Saved*

Mayor Arthur Naftalin

FIVE YEARS AGO we were embroiled in a hard-fought but successful struggle to save General Hospital. Now the existence of General Hospital is once again threatened and unless we act quickly we could lose this magnificent institution.

To close General Hospital would be a community disaster, the result of the public's failure to appreciate the indispensable functions the hospital performs.

In the past five years the need for General has not diminished; it has grown. This is especially significant because five years ago there were many predictions that, with the coming of Medicare, much of the need for General would fade away.

But General has continued to grow because it provides a broad variety of services that people need. It continues to build a fine reputation as a treatment and training center, handling in sympathetic and dedicated fashion the medical requirements of a large segment of our city's population.

General Hospital has been a major institution for 80 years, but many citizens still have only a partial awareness of how the institution is organized and of the services and functions it performs.

Its operation involves the delicate meshing of many resources, all of which are essential for its continued success.

The Staff

The permanent full-time staff of 49 specialists is employed jointly by the County and the University of Minnesota; they direct the work of the residents, interns, undergraduate medical students and other technical personnel in various stages of training.

Residents

The staff includes 66 residents. They are engaged by the county, but they also have status as medical fellows at the University of Minnesota, an arrangement that serves to attract men and women of unusually strong ability, who come to us because they are seeking opportunities for advanced training in all the specialized services that make up the broad practice of medicine. It is estimated that 45 per cent of all specialists and 25 per cent of all general practitioners in Hennepin County received all or part of their training at General.

Interns

The intern group that complements the residency staff currently numbers 48. In the past fifteen years, General has been one of only three large hospitals in the United States that *never failed* to fill its entire intern quota. During this period it has filled a toal of 606 rotating internships.

*Presented to The Forty-Eighth Annual Senior Meeting of the Minneapolis Academy of Medicine. Monday, January 15, 1968. The Minneapolis Club.

Paramedical Personnel

But General Hospital trains not only doctors. It also trains annually 600 students as hospital and medical specialists—nurses, laboratory technicians, x-ray technicians, anesthetists, medical and psychiatric social workers, psychologists, pharmacists, physical therapists and hospital administrators.

Finally, the entire training program has the continuing participation of 334 community physicians. These practitioners contribute thousands of hours of free service in caring for patients and in teaching residents, interns, clerks, and technicians. This provides a measure of medical consultation available at very few other medical centers.

It is the combination of these several levels of professional personnel that makes General Hospital the outstanding medical center it is. The county provides the facility and the patients, the University of Minnesota assists in organizing the medical program and in attracting needed professional staff, and the community provides the reservoir of medical knowledge and experience. All these balanced elements are essential for the hospital's success.

If General Should Die

Private Hospitals

If General should die, could our private city hospitals attract a similar complement of 114 young American medical trainees? Consider these facts: It has been estimated that our city's private hospitals are now spending five dollars a day or more per patient to hire training chiefs and run educational programs to attract interns and residents. How are they faring?

St. Barnabas and Swedish Hospitals sought 20 interns this year; they will have nine, all foreign graduates from the Philippines, India and Latin-America; and there will be twelve residents, nine of them foreign. Northwestern sought 12 interns and obtained four, two foreign; it also has two residents from India. Mt. Sinai has four interns and 19 residents, all but one foreign; Fairview has five residents, all foreign; St. Mary's had 14 openings and filled 11 of them with Americans.

The word "foreign" is not used here in a demeaning sense but to emphasize that foreign graduates do not usually practice here after they complete their training. In contrast, American doctors tend to settle not where they attend medical school but where they complete their final training, whether it be internship or residency.

The Emergency Role

Many of our private hospitals now plan to expand their training facilities, and it is only fair to say that they may be able to attract more interns and residents than formerly.

But the judgment of leading medical men in our area is that it would be tragic to take General out of the mainstream of producing our area's physicians. Furthermore, they maintain that our private hospitals are not really geared to handling General's 24-hour-a-day emergency role as a county hospital facility. During 1967, General handled a total of 70,000 separate emergencies, providing care without reservation, to anyone in need, regardless of residency.

The city's other emergency facilities located at Southdale, North Memorial and Methodist, are all private facilities and are not geared to handle the number of emergencies that General does.

Yet General's emergency role is only one of its many vital functions.

Its Role for the Welfare Agencies

The average bed capacity at General is 394; its average annual occupancy is 80 per cent. Occupancy is lowest (50 to 70 per cent) in pediatrics and obstetrics, a fact which bespeaks the changing and aging character of our population; occupancy exceeds 90 per cent in surgery, trauma (accidents) and male medical wards; and it ranges substantially upwards of 100 per cent in psychiatry, which means beds overflowing in halls and aisles. Five operating rooms work around the clock to do 3,700 procedures annually; private hospitals would use 10 to 14 rooms for the same load.

The hospital provides care for patients in categorical aid programs and in Medicare and for those referred to it by other welfare agencies such as the Hennepin County Welfare Board which then reimburses the hospital.

Contagious Diseases

General also cares for patients with contagious diseases. Such cases are often ex-

tremely difficult, disruptive, or dangerous for the voluntary hospital to provide adequate facilities to isolate and treat. Among the contagious diseases treated in 1967 were meningitis, tuberculosis, gonorrhea, syphilis and hepatitis.

Dialysis Center

General has three other functions I would like to describe very briefly. First, General offers a comprehensive variety of services that any private hospital would be hard put to duplicate. It is the nation's second largest dialysis center for impaired kidneys; it provides special services in hyperbaric medicine, which is that ultra-modern high pressure facility for surgery to force oxygen into body cells and tissues under the same kind of pressure as is exerted 66 feet beneath the sea.

Disaster Center

General Hospital has intensive care units for massive burns and coronary cases; it is an effective suicide prevention center with a special phone that rings many times a day; it is also our area's poison control center.

Second, General is very much an outpatient hospital. It acts as family physician to over 40,000 persons in our community, who consider it just that in our age of mobile populations with their changing patterns of personal medical care. If General dies, could the physicians of our community handle such an added caseload?

Mental Health Facility

And, third, General is further recognized as one of our nation's leading rescue stations for troubled minds; it is considered one of the ten outstanding mental health services in the country.

It has an absolute open-door policy, providing both outpatient and inpatient psychiatric services to anyone in need, as last year's 19,500 outpatient psychiatric visits will attest. Psychiatry is its one service which is used more by suburban than city residents.

The Cost

Five years ago we shifted management of the hospital from the City to the County. That step was essential at that time; but it accomplished only a part of the job of saving the hospital, and it created some new problems, which are now becoming acute.

It resulted in the introduction of the use principle as the basis for financing the hospital, including the costs of the training program. As a result, Minneapolis taxpayers pay four times as much as suburbanites towards the $13.07 million dollar budget for 1968. City residents will be taxed 14.02 mills on their property taxes; suburbanites, 3.2 mills.

The budget problem is further aggravated in that General cannot continue to operate in its present ugly, aged and obsolete plant much longer. It must either rehabilitate its present facilities, which have been shown to be almost impossible, or build new ones; but the money is simply not in sight. One may legitimately ask if such new and costly facilities are really needed in this day of medicare and hospital insurance when government or insurance paid care is available to most persons in private hospitals? What should its new, expanded role be?

The emphatic answer in my mind is that the hospital is indispensable, but the Planning Agency for the Hospitals of Metropolitan Minneapolis has commissioned a study to determine if the hospital is needed, and, if so, what kind of facilities should be planned.

Although the study findings will not be available until the end of the summer, a public referendum has been ordered for the November 5 election ballot as to whether a new general hospital should be built.

The evidence is almost certain to be overwhelmingly in favor of continuing the hospital; but this study will not be completed until late August, allowing only a few weeks for the public to become familiar with the findings of the study before voting.

Alternative

The referendum should be postponed until at least after the 1969 legislative session, at which the entire matter should be reviewed again.*

General Hospital is more than a county concern. Its loss would adversely affect the entire state and region and would seriously complicate plans presently being considered for develop-

*Editor's note: Since the Mayor's speech, the Board of Hennepin County Commissioners on February 20, 1968, rescinded their prior action calling for a referendum in the fall of 1968 and postponed the referendum until such time as the Board and the community have had sufficient opportunity to consider the findings of the Booz-Allen-Hamilton study.

ment of a new medical school. Its loss would also adversely affect the continued supply of physicians for the state.

Responsibility of the State

The state must recognize a responsibility to ensure the continuation of the institution on a financing basis that is fair and equitable to everyone who benefits from the institution, whether as patient or as member of the public receiving improved medical care as the result of the hospital's world famous training program. It is also essential that action towards a new building be taken quickly, as it is estimated that it will take three to five years to build a new facility, which would bring us to at least 1972-73.

The New Facility

The new facility that must be built will function as a major training center and as a truly, modern comprehensive health center. It should be the central institution for a network that includes satellites serving our new Pilot Center, the Model Neighborhood, and other new social renewal projects.

General's future role might be to serve as a focus for other public health measures, including a much expanded community alcoholic rehabilitation program, offering detoxification treatment of alcoholics. It could also serve for retardation research, drug addiction control, and as a blood testing center for our courts.

Tax Benefits

I know that three voluntary medical complexes are in various stages of planning and that there are some who see these associations assuming some of the functions General currently provides. Whatever these complexes achieve, they will not be able to replace General Hospital.

No voluntary hospital can be given the tax support that General now enjoys. Also, a host of problems relating to liability in the management of public responsibilities and immunity would be difficult for voluntary hospitals to achieve.

Institutional Practice

Unlike our private hospitals to which patients are sent by their own physicians for specific treatment or surgery, General believes in the institutional practice of medicine; it caters to the year-round inpatient and outpatient health needs of the individual—and this is important when we realize that General is basically the hospital of the poor, the medically indigent, and those with only moderate incomes insufficient to pay large medical bills.

At General, all fees depend upon income. In 1964, 78 per cent of General's expenses were contributed by local taxes; whereas in 1968, only 53 per cent were contributed by local taxes. It would further appear that in the future, local taxes for support will be reduced to an even smaller proportion of the total budget, describing as further contributions by other third party payees, such as Medicare, rise. It is significant to note that under all of our categorical aid programs more than 20 per cent of our citizens voluntarily choose General as the hospital to which they *wish* to be sent, despite the opportunity to go anywhere they please.

In the light of all these factors, I believe we must launch a community-wide crusade to support General Hospital—to rebuild it completely, to move it, if necessary, but to keep its location in downtown Minneapolis.

I recommend that we dispense with the referendum, that we enlist instead the cooperation and support of the state legislature in developing a direct and constructive program for the continuing future of the hospital. General should be financed on a countywide basis, with all residents within the county sharing on an equitable basis, because all residents benefit from this institution.

If General dies, some agency, some level of government will still have to provide most of the services—such as those in emergency, contagion, poison control, disaster. This would require new, costly facilities, whether there is a General or not. If General closes at a time when the area population spirals upward, patients throughout the county will quickly feel the impact, in the form of an acute doctor shortage.

Therefore I appeal to all the members of the Academy and to everyone in the medical and allied professions to give unstinting support to an immediate drive for a massive public education campaign on the need to save the General Hospital and to enlist the active backing of local, state and national authorities.

b.i.d.

If your objective in the use of a broad-spectrum antibiotic is prolonged action, with high blood levels, consider DECLOMYCIN 300 mg b.i.d.

The maintenance dosage of DECLOMYCIN 300 mg can be kept at this convenient schedule because of its unusually high effective blood and tissue levels.

In clinical practice, blood levels produced by a therapeutic dose of DECLOMYCIN are high, prolonged, and effective, because of high serum binding and slow renal clearance.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Lederle

Prescribing information on next page.

DECLOMYCIN
DEMETHYLCHLORTETRACYCLINE
b.i.d.

DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines when the offending organisms are tetracycline-sensitive.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning—In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions—Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects—Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

In the treatment of syphilis a dosage schedule of a total of 12 to 18 Gm given in equally divided doses over a period of 10 to 15 days should be followed. Close follow-up observation of the patient is recommended, including appropriate laboratory tests, since demethylchlortetracycline has not had adequate evaluation in all stages of syphilis. Spinal fluid examination should be included as part of this follow-up.

Acute gonococcal anterior urethritis in males has been treated effectively with a single dose of 600-900 mg of DECLOMYCIN Demethylchlortetracycline. Individuals unable to tolerate large single doses due to gastrointestinal side effects may be treated with 150 mg every 6 hours for a minimum of 4 doses or 300 mg every 12 hours for a minimum of 2 doses. Females should be treated with a dosage of 150 mg every 6 hours or 300 mg every 12 hours until a cure is effected.

Primary Atypical Pneumonia (Eaton Agent): The average adult daily dosage is 900 mg in 3 divided doses for six days.

Gram-Negative Septicemia

at

St. Mary's Hospital, Duluth, Minnesota*
(1964-1966)

GRAM-NEGATIVE septicemia is a common complication of the hospital environment. Studies in several large centers have listed septicemia as a second most common cause of death among hospitalized medical and surgical patients.[1] The septicemia syndrome is caused by the release into the blood of bacterial endotoxin** which directly and indirectly mediates the development of a characteristic clinical syndrome in many patients.

The effects of the endotoxin-producing bacteria on the human organism are best classified according to the clinical symptomatology exhibited and the course of the illness leading either to death or to recovery. Two classes of response to the septic gram-negative invader emerge.

Class I: Acute Bacteremia

This first category of clinical response to the gram-negative invader may be divided into two distinct types, but for the purposes of this report, both types are recorded under the Class I definition.

Type A, Post-Manipulation Bacteremia, is described by those patients whose presenting symptoms include a fever over 101°, perhaps a shaking chill, diaphoresis, possibly some nausea, a feeling of decreased well being, anorexia and listlessness. The blood culture may not be positive; the bacteremia is episodic and relatively limited in duration and severity; and the recovery is rapid. Aside from fever, leukocytosis, and a positive blood culture, the patient has few laboratory or clinical findings. After one or several episodes, he either spontaneously recovers, or is perhaps treated with a broad-spectrum antibiotic with a prompt fall in temperature and complete recovery. Notably absent in such a patient is hypotension, shock, confusion, tachypnea or collapse.

Type B, Progressive Bacteremia, includes those patients with fever, a severe shaking chill, tachycardia and confusion. Early the skin may be warm and damp; later it will be pale, cyanotic and clammy. Also observed may be moderate tachypnea, moderate hypotension, often nausea, vomiting or diarrhea. Oliguria may be noted. These signs, combined with an anxious expression and restlessness, are clear indicators of an acute, serious illness. Blood cultures are more often positive in this group than in Type A, indicative of greater quantities of bacteria spilled more frequently into the blood stream. Fever, leukocytosis, acidosis, deepening shock and decreasing urinary flow indicate a relentless progression. Untreated, the majority of such patients eventually succumb, usually within 10 days. A few never exhibit hypotension and have relatively warm extremities and adequate urinary output. Yet many of these patients die. In most series, 40-50 per cent in this category do not recover.[1]

Class II: Acute Collapse Reaction

Patients presenting this response are seen as an acute corpulmonale reaction to the presence of endotoxin-producing bacteria in the vascular system.[2] These patients are suddenly critically ill: tachypneic, often deeply cyanotic, confused to comatose, severely hypotensive, with oliguria or anuria, and in complete vascular collapse. Rapid development of acidosis, leukocytosis, electrocardiographic changes suggesting right heart strain, decreased pulmonary vascularity, bronchospasm, and distended neck veins point strongly toward pulmonary embolism as the etiology. However, at post-

*Prize Essay, Duluth Surgical Society, May, 1967.
**See Test Your Word Score Page 797.

mortem examination only a severe infection is present and no emboli are found. This manifestation of gram-negative septicemia has only recently been described, but it may well account for many sudden hospital deaths previously listed as myocardial or pulmonary in etiology. Death occurs in a matter of hours in nearly 100% of such patients.

Materials and Methods

From May, 1964, through December, 1966 70 adult and 14 pediatric patients at St. Mary's Hospital provided 84 positive blood cultures for gram-negative bacteria, based on blood samples drawn before and after death. A relatively consistent distribution of positive cultures was noted, with 17 reported between May and December, 1964, 30 in 1965, and 37 in 1966. The hospital record of each patient was studied to observe the clinical manifestations of the gram-negative septicemia syndrome. Treatment employed was also studied but will not be discussed here. Other valuable information was obtained from the necropsy summary. The clinical manifestations and associations were listed for each patient according to the following definitions:

1. *Presence of a shaking chill* (so described in the nurses' or physicians' notes)
2. *Temperature* (over 101°)
3. *Hypotension* (less than 90 mm Hg)
4. *Tachycardia* (heart rate over 100/minute)
5. *Confusion* (as noted by nurses)
6. *Clinical shock* (cold extremities, diaphoresis, pallor)
7. *Tachypnea* (respiratory rate greater than 26/minute)
8. *Nausea, vomiting or diarrhea*
9. *Reduced renal output* (oliguria - anuria; below 450cc/day)
10. *Indwelling catheter*

Other parameters studied included: (1) the portal of entry of the bacteria, (2) the number of patients falling into Class II, (3) diseases associated, (4) and the relationship between hypotension and death.

Two broad categories of patients, adults, and children were studied. Medical, surgical and Ob-Gyn patients made up the adult group. Because of the great differences in response of infants to septic invaders, the pediatric age group was divided into those patients under one month of age and those over one month.

Results and Discussion

The presence of gram-negative invaders in the blood was best shown to be clinically correlated with three readily measured parameters: temperature, heart rate, and respiratory rate. Eighty per cent of those patients in the study had a temperature over 101° (Table 1). Seventy-seven per cent had a heart rate over 100, and 71 per cent a respiratory rate greater than 26/minute. Temperature is the most valuable clinical indicator of sepsis; if it is very high, especially in the elderly, a diagnosis of septicemia is probable. Confusion is another prominent symptom, especially in the elderly patient who was lucid before the onset of septicemia. Children over one month of age present essentially the same

TABLE I
Clinical Signs in Gram-Negative Septicemia
Adults

Clinical Sign	Medicine	Surgery	Ob-Gyn	Totals	Per Cent
Shaking Chill	18	13	4	35	50
Temp. over 101°	33	16	7	56	80
Hypotension	17	7	0	24	34.3
Tachycardia	32	15	7	54	77
Confusion	29	11	2	42	60

picture as adults.

Clinical Symptoms

Children less than one month of age exhibit few of the classical signs of septicemia. Table 2 illustrates the paucity of symptoms found in the infant in the presence of septicemia. Tachypnea occurred in 60 per cent of the patients in this group and was the only symptom present in several cases. None had a temperature over 101°. Only one infant had a shaking chill and only two had a tachycardia. Other factors, such as neonatal jaundice, poor eating, and failure to thrive, were more often seen. Persistent tachypnea in the very young child should encourage a search for sepsis.

The classical "shaking chill" occurred in 50 per cent of the adults but in only 10 per cent of the infants. Its presence is pathognomic of a septicemia and in most cases was recognized as such. Although this symptom is very helpful in diagnosis, it should *not* be relied upon as the most sensitive indicator of sepsis.

TABLE 2
Clinical Signs in Gram-Negative Septicemia
Children

Clinical Sign	Under one month of age	Per Cent	Over one month (to age 16)	Per Cent
Shaking chill	1	10	1	25
Temp. over 101°	0	0	3	75

Tachypnea	6	60	1	25
Nausea, etc.	0	0	2	50
Oliguria	0	0	0	0
Catheter	0	0	2	50
Deaths	7	70	2	50
Recovered	3	30	2	50
Number patients	10	100	4	100

The Organisms

Eleven different organisms in pure culture and several mixed gram-negative infections were found in adults (Table 3). Nearly 45 per cent of adult gram-negative septicemias were caused by E. coli. Proteus species were a distant second with a 15 per cent rate of occurrence. E. coli affected 60 per cent of the new-born group (in pure culture) while an additional 20 per cent were found to have a mixed infection with E. coli one of the agents. Opportunistic, normally saphrophytic organisms, like Pseudomonas species were found in significant association with lymphomas and terminal metastatic disease.

Portal of Entry

The portal of entry of the gram-negative invader was most often the urinary tract (Table 4). The presence of an indwelling catheter should be kept in mind when a source for sepsis is sought. Nearly 25 per cent of the bacteria gained entrance through the peritoneum; 15 per cent came from other areas (skin, bowel, bones, etc.), and only 10 per cent of adults showed no obvious avenue of sepsis. Thus a diligent search by the clinician is most often rewarded.

TABLE 3
Organisms

Agent	Adults	%	Children (over 1 mo.)	%	Children (under 1 mo.)	%
Eschereschia coli	31	44.3	1	25	6	60

Associated Disease

In 39 per cent of the cases, adult sepsis was associated with disease which, in itself would often be fatal. Fourteen individuals had cancer, many in advanced stages of the disease. Two patients had cirrhosis, five diabetes mellitus, and six others a chronic debilitating disease such as multiple sclerosis. Many of these patients had indwelling catheters, constituting a ready beach-head for bacterial invasion. Early diagnosis and treatment of such patients may result in added months or years of useful life.

Morbidity

Twenty-four of the adults developed hypotension during the course of their septicemia. Of these 24, 21 died (86.6 per cent). Many of these patients did not receive heroic treatment; but in spite of heroic measures, no authors have reported salvage of more than 50 per cent of these patients. Bearing in mind the possible disastrous effects of spillage of bacterial organisms into the blood, early treatment of known gram-negative infections (such as cystitis and pyelonephritis) will do much to lessen the incidence of such severe reactions.

Twelve patients presented the Class II or Acute Collapse Reaction, one of whom survived. Three were infants less than two weeks of age. Two case reports of patients whose responses fall into Class II are illustrative of what the clinician might find on the ward.

Case Reports

Case 1

A 69-year-old Indian woman was brought to the St. Mary's Hospital emergency room comatose and in shock on 9/8/66. The patient had been found in this condition in bed at home. In February, 1966, she had had an open reduction of a subtrochanteric fracture of her right hip. During that admission an indwelling Foley catheter had been used for ten days without complication. All laboratory reports had been within normal limits. The patient had had a previous history of Potts disease, and numerous cultures of sputa for acid-fast bacilli had been negative. She had been discharged in April, 1966. On her 9/8/66 admission the patient was deeply comatose, pale, cold and clammy; the blood pressure was unobtainable; the pupils were dilated and fixed. The heart rate was 82 and regular. Respirations were 26/minute and described as "short." An electrocardiogram showed sinus arrhythmia. The white blood cell count was 14,600; the differential: 5 myelocytes, 7 metamyelocytes, 17 non-segs, 29 segmented forms, 36 lymphs, and 6 monocytes. The hemoglobin was 16.3 —121%. Twenty-five minutes after admission respiration ceased and she could not be revived. The attending physician felt that she died of a massive cerebrovascular accident. At necropsy over 1000 colonies of E. coli per cc. were cultured from the blood. Acute bilateral pyelonephritis with bilateral necrotizing papillitis and chronic cystitis were found.

Comment: The death of this patient in a matter of hours illustrates the overwhelming effect of endotoxin on the body integrity of some patients. This patient was not acutely tachypneic on admission, not described as being in deep cyanosis, but was in profound peripheral vascular collapse. The significant left shift of the differential white blood cell count and the hemoconcentration suggest an acute hypovolemia. This picture is often seen in gram-negative septicemia with shock and forms part of the basis for treatment with plasma, dextran and other volume expanders as proposed by several authors.[1,3,4]

Case 2

A 57-year-old white woman with a diagnosis of acute lymphatic leukemia, in protective isolation, developed right pleuritic chest pain at 9:00 a.m. on 12/1/66. She was acutely dyspneic, cyanotic, restless and dizzy. The blood pressure was 70 systolic, 50 diastolic; the heart rate was 150; the respirations were 36-48/minute; the temperature was 104°. A chest film showed a right middle lobe and left lower lobe infiltrate. Massive doses of penicillin, chloromycetin, fluids and isoproterynol were used in treatment. The dyspnea and cyanosis deepened, and the patient expired with extreme tachypnea and cyanosis at 8:00 p.m. that night, 11 hours from the onset of

TABLE 4
Portal of Entry

Route	Adults	%	Children (over 1 mo.)	%	Children (under 1 mo.)	%
Urinary Tract	35	50	1	25	0	0
Peritoneum	17	24.3	0	0	0	0
Other (skin, lung GI, ortho, etc.)	11	15.7	1	25	8	80
Unknown	7	10	2	50	1	10

the illness. Blood cultures drawn before and after the antibiotic regimen was begun, grew out more than 1000 colonies of *Pseudomonas aeruginosa*. At necropsy bilateral bronchopneumonia, acute lymphatic leukemia and a massive Pseudomonas septicemia were found.

Comment: The ease of confusion with pulmonary embolism in this patient is apparent. Others in Class II presented a similar picture. If pulmonary embolism is suspected but the temperature is elevated, sepsis should be entertained as a probable etiology for the clinical state and heroic measures of treatment begun.

Of the eight adults and four children shown to manifest the severe reaction of Class II, only one adult survived. This patient was treated with massive doses of broad-spectrum antibiotics, large doses of steroids, and intensive nursing care. After several days she responded and recovered uneventfully. Thus, although a Class II reaction to gram-negative septicemia carries a grave prognosis, early and persistent therapy may result in an occasional survival.

The number of diagnostic impressions listed in the 12 patients in Class II is almost as long as the list of patients. Several were thought to have pulmonary embolism and one a cerebrovascular accident; in others the attending physician ascribed a myocardial etiology as the prime diagnosis. In most of the patients the diagnosis was made at necropsy. Other severe disease processes were present, concurrently, in several patients. Two had leukemia, one patient acute pancreatitis and fatty cirrhosis, one a perirectal abcess, and one acute bilateral pyelonephritis.

Conclusions

Eighty-four blood cultures at St. Mary's Hospital, Duluth, Minnesota, (drawn from 84 patients) were positive for gram-negative organisms between May, 1964, and December, 1966. The charts and/or necropsy summaries on each patient were reviewed, noting the clinical course, the bacteria involved, the portal of entry, the treatment, and the prognosis. The following salient conclusions can be drawn:

1. Elevated temperature, tachycardia, tachypnea and confusion occur more often in the presence of a gram-negative septicemia than does the classical shaking chill.
2. Children under the age of one month present with different symptomatology than older children and adults.
3. The main portal of entry of gram-negative bacteria remains the urinary tract.
4. Hypotension occurring during the course of a gram-negative septicemia indicates a grave but not hopeless prognosis.

Two broad classes of response to the invasion of the gram-negative bacteria into the blood can be listed. The first class is best considered in two subclasses: Type A, Post Manipulation Bacteremia, and Type B, Progressive Bacteremia. The second Class, Acute Collapse Reaction, includes patients with a much more fulminant reaction. Two cases in this group are presented. It is postulated by the author that several similar cases of sepsis might pass unnoticed each year in the average 500-bed hospital, the clinical diagnostic impression being pulmonary embolism, massive cerebrovascular accident, or massive myocardial infarction.

Popular Fallacies

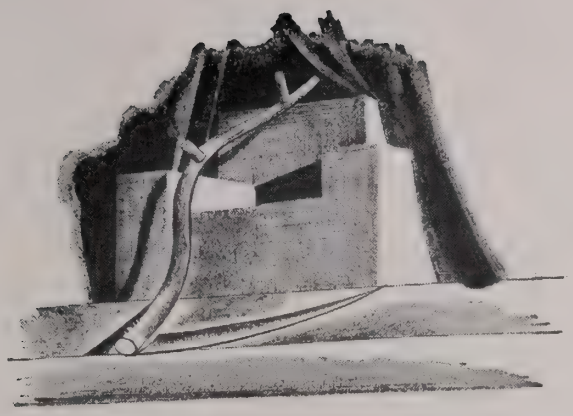
Settlers Guessed About Medicine

American medical tradition stems from an age very different from the one in which we now live, points out TODAY'S HEALTH GUIDE, the American Medical Association's manual of health information for the American family.

The early settlers, living remote from civilization, turned to the traditions of their ancestral homelands and to the methods of the Indians, and came up with a medical lore all their own. Their ideas of prevention and treatment were not all wrong, but often they did more harm than good. Some of the common misconceptions of the frontier era have carried over into modern times.

TODAY'S HEALTH GUIDE lists the facts about some of these misconceptions—

- Blood pressure of 100 plus the individual's age is *not* the normal value.
- Red meats and alcohol are *not* necessarily harmful to those with high blood pressure.
- Fish is *not* a brain food, it is simply a good food for all parts of the body.
- Sweets, while possibly detrimental to the teeth, are *not* the sole cause of tooth decay.
- There is no reason of health why one should not eat shellfish and ice cream at the same meal, provided neither of them is spoiled.
- Lemons, oranges, tomatoes and grapefruit do *not* cause "acidity" of the body.
- Fat people are *not* necessarily carefree and jolly.
- Being fat and 40 and feeling well does *not* constitute a good reason for declining to lose weight.
- It is *not* necessarily unwise to drink water with your meals, if you don't gulp it.
- Gargles and mouthwashes do *not* kill the germs in the mouth or throat.
- Boils are *not* due to impure blood.
- Punctures from rusty nails are no more dangerous than punctures from shiny nails; the danger lies in the germs that either one may introduce.
- Night air is *not* unhealthful. However, it is *not* necessary to open the windows of your bedroom wide at night, especially when it is cold.
- Whiskey with aspirin is *not* a good remedy for a cold. The cold might improve in spite of it.



Disease as Reprisal II

Why was Jehoram smitten with a bowel disease?
He had committed acts that were evil in the eyes of the Lord.
And after all this the Lord smote him in his bowels with an incurable disease.
And it came to pass, that in process of time, after the end of two years, his bowels fell out by reason of his sickness: so he died of sore diseases. (II Chronicles, 21:18, 19)

In Memoriam

Not dead, but gone before.—Rogers

WILLIAM E. TAYLOR, M.D.

Dr. William Taylor, 43, Minneapolis obstetrician-gynecologist, died February 24. He received his medical degree at the University of Minnesota and had practiced obstetrics and gynecology since 1954.

He was on the staff of St. Mary's, Glenwood Hills and Methodist hospitals and was third vice chairman of the third district DFL. Dr. Taylor was a member of the Hennepin County Medical Society, American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, three sons and three daughters.

FRED J. PRATT, SR. M.D.

Dr. Fred J. Pratt, 91, retired otolaryngologist, died January 17. Born in Jackson, Michigan, Dr. Pratt obtained his medical degree at the University of Michigan.

He was a member of the Minnesota Academy of Ophthalmology and Otolaryngology, the American Medical Association, Hennepin County Medical Society and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his son, Dr. Fred J. Pratt, Jr.

HERBERT H. BUSHER, M.D.

Dr. Herbert H. Busher, 75, St. Paul surgeon, died February 26. He graduated from the University of Minnesota Medical School in 1919 and interned at the University of Minnesota.

Dr. Busher was a member of the American College of Surgery, the Ramsey County Medical Society, the American Medical Association and was a Life Member of the Minnesota State Medical Association. He was to have been accepted as a member of the 50 Club of the Minnesota State Medical Association last month at the Association's Annual Meeting in Rochester.

He is survived by his wife.

NICOLAY H. SCHELDRUP, M.D.

Dr. Nicolay H. Scheldrup, 94, Minneapolis physician for more than thirty years, died April 9 in Miami, Florida. He started his practice in Granite Falls in 1897 after receiving his medical degree at Rush Medical School, Chicago, and in 1907 moved his practice to Minneapolis.

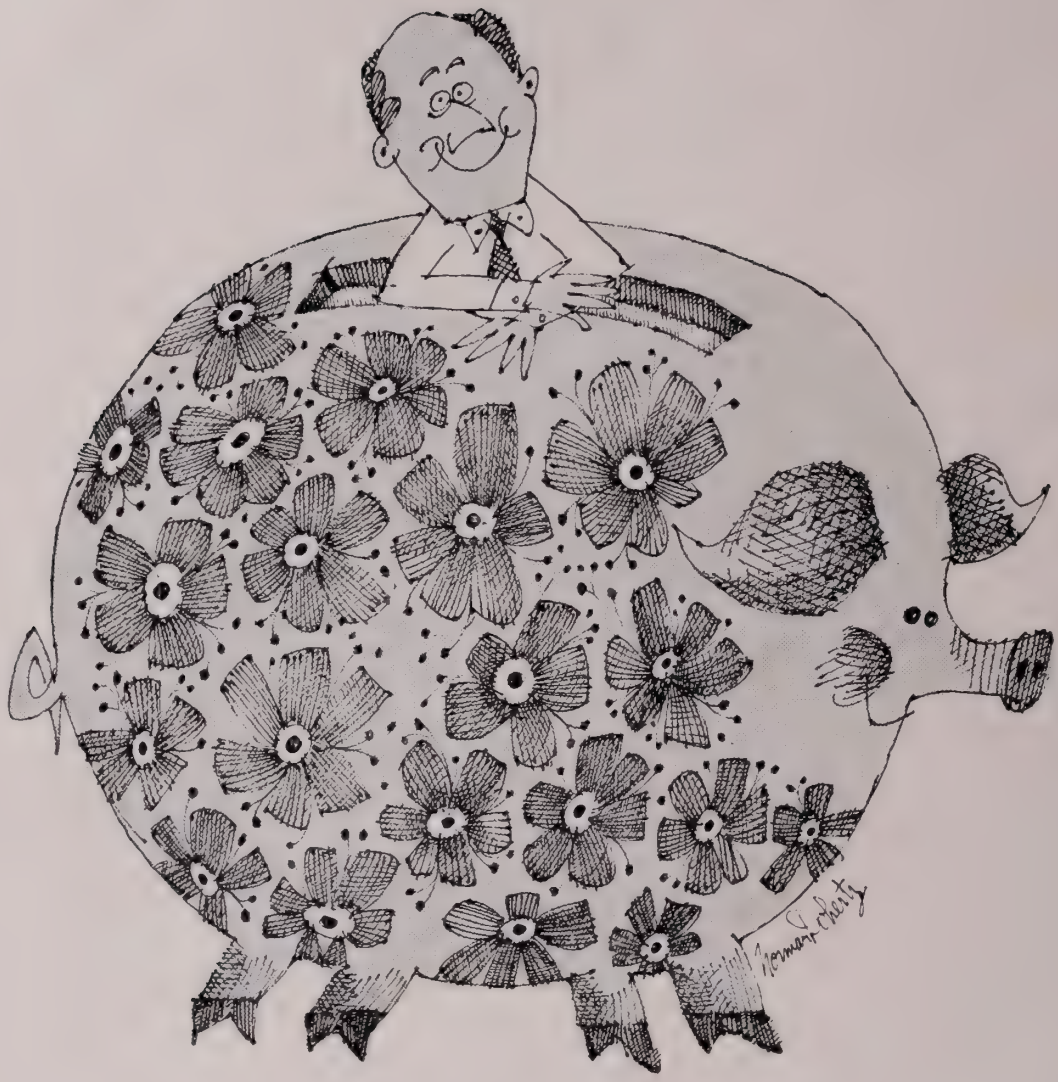
Dr. Scheldrup was a member of the Hennepin County Medical Society and the American Medical Association and a 50 Club and Associate Member of the Minnesota State Medical Association.

He bore the title of Sir having been knighted by the King of Norway for his work with the Norwegians in Minnesota.

He is survived by a daughter and three sons, one of whom is Dr. Eugene W. Scheldrup of Iowa City, Iowa.

GEORGE E. McGEARY, M.D.

Dr. George E. McGeary, 74, Minneapolis physician died May 2, 1967, in Florida. He was born in St. Paul, Minnesota, and obtained his medical degree at the University of Minnesota.



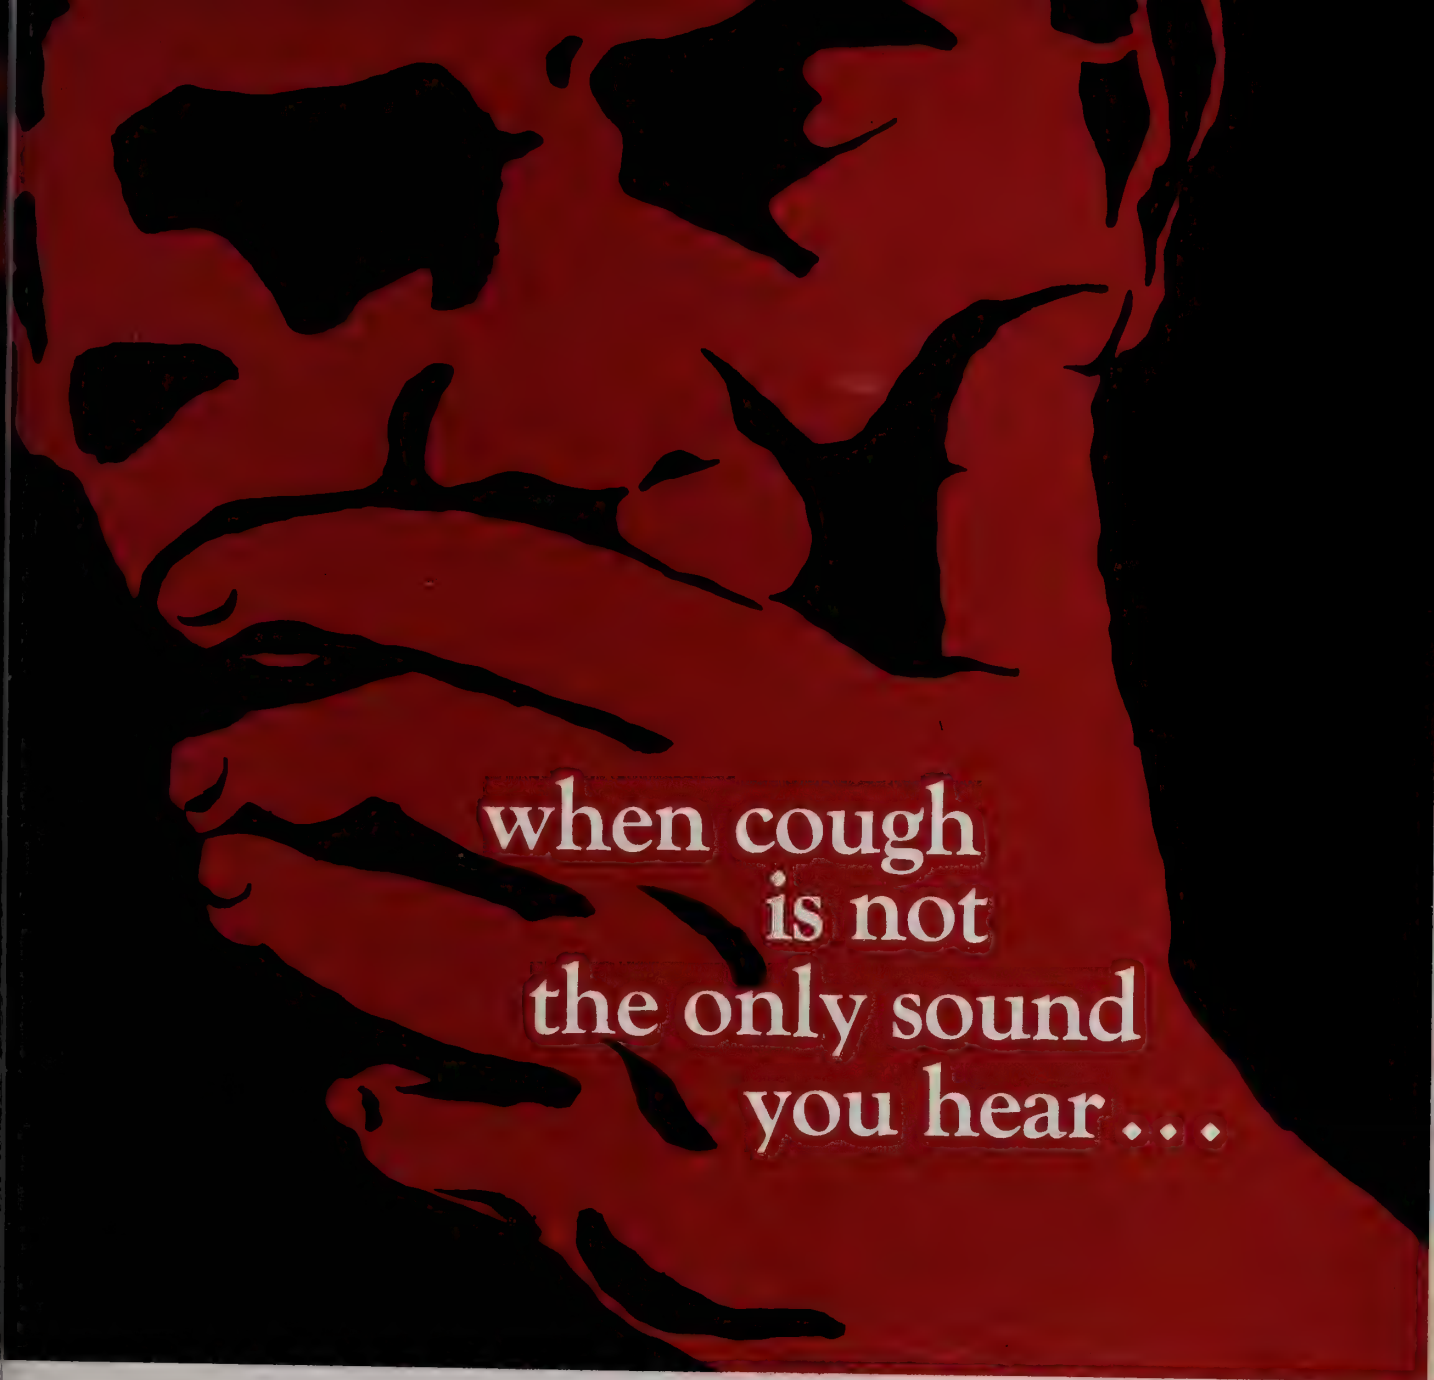
Dr. McGeary was a member of the Hennepin County Medical Society and the American Medical Association and was an Associate Member of the Minnesota State Medical Association.

VIRGIL J. SCHWARTZ, M.D.

Dr. Virgil J. Schwartz, 73, well-known ophthalmologist, died April 17, after a long illness. Dr. Schwartz came to the United States in 1900 and practiced medicine in Minneapolis for over forty years. He was a graduate of the University of Minnesota Medical School, where he served as a teacher of ophthalmology.

He was a member of the American College of Surgeons, the American Academy of Ophthalmology and Otolaryngology, the American Medical Association and the Hennepin County Medical Society. He was also a Life Member of the Minnesota State Medical Association and was honored posthumously as a 50 Club Member during the Association's Annual Meeting in Rochester.

He is survived by his wife and a daughter.



The first thing to save for your old age is you!

Everyone dreams of a pleasant retirement. And practical people save for it. But what good are plans and dreams if you aren't around to enjoy them? Be smart and have a complete health checkup every year. 1,400,000 people living today are cured of cancer. And a yearly checkup could save many thousands more. Plan now to have a future. Make an appointment today for your health checkup.

OMNI-TUSS® b.i.d.

. . . **because** OMNI-TUSS is indicated for cough associated with upper respiratory tract infections, bronchitis, bronchiectasis, bronchial asthma, emphysema, sinusitis and rhinitis, hay fever, or other allergic conditions. Any of these conditions may exhibit the general symptom syndrome—coughing, wheezing, bronchospasm, and tenacious mucus—which may benefit from the antitussive, bronchodilative, antihistaminic, and expectorant action of Omni-Tuss.

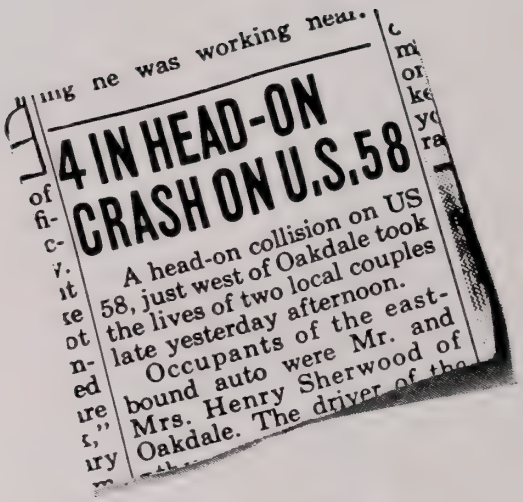
The therapeutic usefulness of Omni-Tuss is enhanced by a unique resin complex formulation providing the clinically desirable advantages of: (1) uniform drug availability throughout an extended period, (2) 8 to 12 hours of symptomatic control, (3) minimal dosage requirement, (4) minimal side effects.

Economical, efficient **b.i.d.** dosage—extremely well-tolerated by children, 6-12, and adults.

'Omni Tuss' Suspension: Each teaspoonful (5 cc.) contains 10 mg. codeine (Warning: May be habit-forming), 5 mg. phenyltoloxamine, 3 mg. chlorpheniramine, 25 mg. ephedrine, all as cation exchange resin complexes of sulfonated polystyrene, and 20 mg. guaiacol carbonate.

Available on prescription only. Class X exempt narcotic. Permissible on oral prescription.

Dosage: *Adults:* 1 teaspoonful (5 cc.) q12h.
Children (6-12 *years*)*:* ½ teaspoonful q12h.



Side Effects: Minimal, but when encountered may include jitteriness, nausea, drying of mouth, insomnia, constipation, which disappear upon adjustment of the dose or discontinuance of treatment.

Precautions and Contraindications: For complete detailed information, refer to package insert or official brochure.

The Minnesota Thoracic Society and the Minnesota Respiratory Health Association announce a second award contest for medical students, interns and resident physicians in Minnesota.

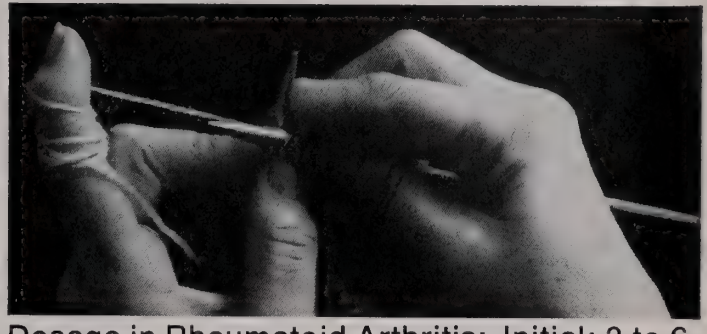
(A) An award of $200.00 is offered for the best paper submitted by a senior medical student or intern on some aspect of respiratory disease, preferably based upon laboratory or clinical investigation.

(B) An award of $300.00 is offered for the best paper submitted by a resident physician based upon clinical or laboratory investigation in the area of respiratory disease.

Further information may be obtained from the Secretary. Entries should be submitted by September 1, 1968 to: David E. Dines, M.D., Secretary, Minnesota Thoracic Society, Mayo Clinic, Rochester, Minnesota.

Butazolidin® alka
in rheumatoid arthritis.

If it doesn't work in a week,
forget it.



But don't forget this about Butazolidin alka

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently. Large doses of Butazolidin alka are contraindicated in glaucoma.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Persistent or severe dyspepsia may indicate peptic ulcer; perform upper gastrointestinal x-ray diagnostic tests if drug is continued. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with caution in the first trimester of pregnancy and in patients with thyroid disease.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make complete blood counts at weekly intervals during early therapy and at 2-week intervals thereafter. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The more common are nausea and edema. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately before or after meals or with milk to minimize gastric upset. Drug rash occasionally occurs. If it does, promptly discontinue the drug. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), or a generalized allergic reaction similar to serum sickness may occur and require permanent withdrawal of medication. Agranulocytosis can occur suddenly in spite of regular, repeated normal white counts. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, hypersensitivity angiitis, pericarditis and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Rheumatoid Arthritis: Initial: 3 to 6 capsules daily in 3 or 4 equal doses. Trial period: 1 week. Maintenance dosage should not exceed 4 capsules daily; response is often achieved with 1 or 2 capsules daily.

In selecting appropriate dosage in any specific case, consideration should be given to the patient's weight, general health, age and any other factors influencing drug response. (B)46-070-A

How to turn a 14-year-old boy into a hardened criminal.

Just forget your keys in your car one day.

Tempt some fourteen-year-old boy into going for a joyride.

Oh, he could be a good kid — just weak.

And taking your car might be the first time he's ever broken the law.

But the minute he hops behind that wheel and turns the key, his life may be ruined.

He'll drive around for a few hours, endangering the life of every man, woman and child who crosses his path.

He might be caught the very first time he takes a car. Or if he's not caught by the police he'll leave your car somewhere and decide to do it again, and again, until the day he does get caught.

Teen-agers steal more than 1,000 cars every day.

The U. S. Department of Justice and your state and local law-enforcement agencies are concerned.

They know that taking a car for a joyride is just the first step.

Our prisons are filled with men who started out this way. They went on to become thieves, muggers, and even killers.

You can do something to help solve this terrible problem.

Whenever you get out of your car, even for a second, take your keys. Lock your car.

Every time you do this you may keep a good boy from going bad.

ADVERTISING COUNCIL

Don't help a good boy go bad. Lock your car. Take your keys.

History of Medicine

Memories of 30 Years of Group Experience in Anesthesia*

JOHN S. LUNDY, M.D.
Seattle, Washington

I HAVE CHOSEN the title of this talk because I know of no better way for the ready, authoritative and usually pleasant acquisition of extensive knowledge than exposure to the experience of a group of colleagues and fellow workers. Each member of a group such as this contributes, in theory at least, at the same time that he is benefitting from the experience of every other member. In the absence of such a group within one's specialty, one would have to find a substitute in the form of meetings of state, regional or national meetings of a general nature, and that can be pretty poor fare.

I can well remember the paucity of group experience and agencies for the exchange of knowledge in anesthesia, because I started entirely alone in this field and, perforce, developed the group here and other groups elsewhere. Then, when I retired from service at the Mayo Clinic in 1959, I returned to private practice alone.

The Boy Anesthesiologist

I must have had some sort of predestination for the specialty of anesthesiology, or perhaps a genial diathesis toward it, because my first memory of it goes back to 1910, when I visited a dental clinic in Grand Forks, North Dakota, in the course of which the late Dr. J. A. Heidbrink, of Minneapolis, was demonstrating his new invention, the gas machine. A boy of 16 years, I watched him anesthetize a man in a dental chair on the stage of a theater and extract some teeth. When the man awoke he laughed interminably. I said to myself, "He must have given him 'laughing gas.'" That was indeed what Dr. Heidbrink had administered: nitrous oxide and oxygen. I remember how impressed I was.

My father was a pioneer of the American frontier, but I never knew him. He had obtained license No. 55 in the Territory of Dakota, in 1885,[1,2] but died of pneumonia at the age of 35 years when I was 18 months old. The physicians who followed him in practice in Inkster, North Dakota, took a benign and protective interest in me and encouraged me to follow medicine and the doings of physicians in the vicinity. And so I began to give anesthetic agents for a Dr. B. D. Lemery, who had been encouraged to become a physician by my father. He instructed me in the necessity for maintenance of a patent airway, and taught me how to administer the ACE mixture, which was one part alcohol, two parts chloroform, and three parts ether, all together in one bottle.

I never forgot this early experience, and it was recalled to me vividly when two relatively noninflammable general anesthetic agents, Fluothane (halothane) and Penthrane (methoxyflurone), were recently introduced into practice. Memory enabled me to visualize what would have been the delight of the originator of the ACE mixture had he been able to use these two agents supplied in separate containers on a gas machine. As for myself, I have derived much satisfaction from the use of these two agents alone, combined, and with nitrous oxide and oxygen on numerous occasions. I have been able thereby to establish a state of anesthesia which has seemed to me to be more satisfactory than any that I have been able to produce in the past with the general anesthetic agents then available.

*Read before the First Group Meeting of the Section of Anesthesiology of the Mayo Clinic and Mayo Foundation, Rochester, Minnesota, October 28, 1967.

Anesthesia In and Out of School

I administered anesthetic agents for my friend, Dr. Lemery, until I was graduated from the University of North Dakota in 1917. I then entered Rush Medical College. I lived in the Alpha Kappa Kappa fraternity house on the west side of Chicago. My roommate, Dr. Proctor C. Waldo, and I carried out anesthesia in the Presbyterian Hospital in Chicago on a number of occasions for such well-known men as the father of Dr. Evarts A. Graham, for Dr. Arthur Dean Bevan, and for many others, so that after my graduation from medical school, during an internship at the Harper Hospital in Detroit, I was administering anesthetic agents because I was the only one of the group of interns who knew how to manage a gas machine. It was at that hospital that I had my first experience with nurse anesthetists. The department was headed by Dr. James Shannon, a dentist, who understandably stopped his work in anesthesiology shortly after he invented a new clutch for the Cadillac automobile.

Seattle Days: Early Lessons

After my internship I visited the West, which brought me in the fall of 1920 to Seattle, Washington. There I opened an office in the Joshua Green Building. As luck would have it, at the moment I was signing the lease for space in another physician's suite, he asked me if I could give an anesthetic agent. I told him that was the one thing I knew I could do, and he engaged me for the next morning, in Columbus Hospital, in Seattle. Thus I began the practice of medicine for myself, at the first hour of the first day, by giving a general anesthetic agent.

About a year later another man and I attended a convention of the Pacific Coast Association of Anesthetists in Portland, Oregon. The group consisted of six or seven women physicians and two male physicians. We have come a long way from this infinitesimal beginning in Seattle. Now several groups of men associated in anesthesia would be well able to outnumber the little band of tyro anesthesiologists who attended that old-time meeting in Portland.

At the time I began to practice in Seattle one man there, Dr. Louis Maxson, devoted full time to general anesthesia. I made sure that I did not interfere with his clientele, and within a short time I had built up a practice which more than kept me busy. In all cases I kept a record, in duplicate, of the blood pressure, pulse rate, and the rate of respiration.

This type of record-keeping was something new at the time and was greatly admired by the surgeons with whom I worked. It was not long before I found myself with more appointments than I could manage personally, and so I gradually arranged for the services of five men to accommodate my overflow of calls.

I was fortunate enough to be able to devise a plan which proved to be much more successful for all concerned than any arrangement which I have seen or heard of since. Since all calls from surgeons for our services came into my office, they were received by my two office girls, who thereupon tried to complete my schedule for each day. Should it happen that six calls came in for an anesthesia session at 8:00 in the morning on the same day, the result was that each of us was given an assignment. In such an event I of course had nothing to do with the sessions conducted by the others unless a surgeon complained to me that the management of anesthesia for his patient had not conformed to the standards which I had set up for anesthesia in general. I then would call the man who had been in charge of the anesthesia and explain to him that the surgeon had not been satisfied because the session had not been managed according to the standards I was known to use. I would then caution him that if he wished more calls to be referred to him from my office, he would have to conform to my standards of general anesthesia. Such an admonition was sufficient to correct the situation. It was the only hint of a disciplinary measure that was required.

The group practice of anesthesia never fails to be interesting and sometimes lively, but it is possible for the anesthesiologist to be destroyed by his own success. Suppose a man establishes a practice of anesthesiology which becomes so extensive that he must take on partners. To the partners he gives a vote. As soon as he has taken on two associates, he jeopardizes his management of the group, because his voting partners outnumber him. I believe that success is no accident, which means that a manager

is required to see that a group succeeds. One of the most successful medical managements known to me is that instituted by the two Mayo brothers, who governed their institution with firmness, wisdom, justice and, inevitably, notable success.

In my early days at the Mayo Clinic it was the Mayo brothers who decided what would be done. Other members of the staff had votes, in management, but they had better sense than to use them contrary to the wishes or decisions of the Doctors Mayo. I believe that in private groups engaged in anesthesia someone must be at the helm, even if the place of power has to be rotated over the years until one person is found who has a natural ability for successful management. And the salient advantage of experience in such a group emerges in the fact that one man very quickly learns what will succeed and what will fail, and if he is patient and considerate, yet resourceful, he can lead the group along the pathways to success.

Any small group benefits much from an arrangement whereby, usually each year, one member attends meetings of societies away from home and brings back such information as he can obtain for the good of the whole group.

It is wise, I think, to make some provision within a group for continuity of the performance of certain procedures devised by some associate of recognized ability, so that if that person leaves the group, the techniques he originated will not languish. This counsel applies to large groups as well as small ones. I well recall that toward the end of my tenure at the Mayo Clinic I was developing a certain technique for nerve destruction with an insulated needle emplaced by roentgen-ray control. But scarcely anyone else in my group was interested in what I was doing, so that after I left I noticed that some patients followed me elsewhere, because the technique I had used was no longer available at the Mayo Clinic. This was discouraging to me, but the situation still obtains, and a few patients still come to me from far away to seek medical counsel.

The Chief Speaks: Dr. William J. Mayo

In the few years that I was in Seattle when I began to practice anesthesiology I was active in the King County Medical Society. Finally I was appointed editor of the bulletin of that society and increased the number of pages from four to 32, paying expenses by means of advertisements. As a result of this effort I was elected secretary of the King County Medical Society shortly before I left Seattle in 1924. On the night of the election and annual banquet for the retiring president, it happened that Dr. William J. Mayo, who was on his way to Australia and New Zealand, was a guest speaker. As secretary of the society I was seated next to him on the platform, and we talked about ethylene anesthesia. It was clear that this type of anesthesia was not in use at the Mayo Clinic. He asked me to walk to the railway station with him after the meeting, and just as he left for his train to Vancouver he invited me to come to the Mayo Clinic.[3] I did so. In 1923 I had administered ethylene as a general anesthetic agent for the first time to infants who had pyloric spasm. The patients did very well. I reported the series the next year.[4]

I also had administered ethylene for one or two operations on the gallbladder in Portland, Oregon, for the late Dr. Thomas Joyce. In 1966 I arranged an exhibit at the annual meeting of the Washington State Medical Association on blood transfusion, blood banking, and the early history of ethylene anesthesia in the Pacific Northwest, some of the material emerging from the early experiences of which I speak.

At the Mayo Clinic: 1924

Soon after my arrival in Rochester, Minnesota, in March, 1924, I could see that in all likelihood the Mayo Clinic would continue to enlarge impressively, which meant that concomitantly the field of anesthesia within the Clinic would be much expanded indeed, as the years went by. I decided that I would try to make one contribution to anesthesiology for each of the 35 years which lay ahead of me. On the basis of experience in the country and on farms I realized that one must plant several crops if one expects to have one real harvest each year. Hence, I tried to keep five projects in anesthesia going all the time, hoping for one good harvest each year while I was here.

Early Graduate Training

During my early years at the Mayo Clinic it

was the general understanding of all concerned that each fellow, or graduate student, enrolled in the Mayo Graduate School of Medicine, would attempt to obtain an advanced degree in his special field from the University of Minnesota. I supported and encouraged this plan as soon as I was able to establish graduate fellowships in anesthesiology. Each of the fellows in anesthesiology who sought a master's degree succeeded, for the most part. Each fellow, as he assumed his fellowship, was given an individual identifying number. I believe this practice is still followed. Since the autonomy of the American Board of Anesthesiology, Inc., was established in 1941, I am not sure that all fellows of the Mayo Graduate School of Medicine still seek an advanced degree from the University of Minnesota, because they are more concerned, practically, with certification by this board than they are in acquisition of an advanced degree. Yet I believe it is of permanent value and significant of achievement within one's field to be able to append the designations of advanced degrees after one's name. I can say this with complete equanimity, because I do not have any advanced degrees other than honorary ones. I have had to make my way without such prestigious insignia.

Subspecialties in Anesthesiology

I had a plan for the formation of a section devoted to anesthesiology as soon as Dr. Charles F. McCuskey joined me at the Mayo Clinic in 1925. His coming meant that we could provide a certain degree of clinical service in anesthesia to hospitals in which surgeons, obstetricians and dentists of the Mayo Clinic worked. Thereafter, consultants were added to the section which I organized, and I tried to designate a particular field in anesthesiology to which each one could devote the major part of his interest outside his clinical responsibilities. For example, Dr. Ralph M. Tovell became an authority on anesthesia records, so that data could be obtained readily and accurately for study and reports. Dr. E. B. Tuohy covered general physiology, Dr. L. H. Mousel covered the area of the chest, Dr. R. Charles Adams wrote his book on intravenous anesthesia, Dr. T. H. Seldon covered blood transfusion and conducted the new blood bank, and Dr. John A. Paulson supervised the nurse anesthetists. These are a few illustrations. Also, for some 28 years I prepared an annual report of the Section of Anesthesiology, not only for publication in the *Proceedings of the Staff Meetings of the Mayo Clinic*, but for submission *in extenso* to the Board of Governors as well. The latter version was a separate and more detailed account. I have seen no such annual reports from that section recently.

The First Laboratory of Anatomy

By 1927 it became apparent to me that my colleagues and I needed more anatomical knowledge, and I therefore brought about the establishment of a laboratory of anatomy. This I maintained for 20 years without outside help, until I found it was essential that a full-time anatomist be obtained. I persuaded the Board of Governors to secure one: since 1947 the services of a Section of Anatomy headed by an outstanding anatomist have been available to members of the staff.

Blood Transfusion and Blood Bank

In 1933 Dr. C. H. Mayo decided that someone should be directed to take charge of the transfusion of blood to infants, and I was selected. In 1934 I was asked to supervise all work in transfusion.

In 1935 Dr. William Carpenter MacCarty, of Saint Mary's Hospital, allowed me to store citrated blood for transfusion in his laboratory refrigerators at the hospital, and thus was established the first blood bank in North America, as far as I can find out. The Cook County Hospital in Chicago began such a service the next year, in 1936. This incident can be validated, because I reported the establishment of my blood bank in my annual report[5] for 1935. It is thus incontestable that the first blood bank was set up in Rochester at Saint Mary's Hospital.

Anesthesia Abstracts

By 1937 it seemed to me that we ought to have a journal club in the Section of Anesthesiology. I organized one, and assigned papers in the literature to be read by each member of the section, and to be reported on at a meeting of the club. Some of the less intrepid members of the group could not overcome their diffidence sufficiently to make an oral presenta-

tion of what they had read, but since they had prepared these reports and the reports had been typed, it occurred to me that somehow we ought to see that they were published. Such was the inception of what later became *Anesthesia Abstracts,* a successful venture which persisted for some time. Soon Miss Florence A. McQuillen, C.R.N.A., of Chicago, took over all the work involved in the preparation of material for this publication, and she alone produced *Anesthesia Abstracts* from then until 1965, when she finally abandoned the effort, much to my regret.

Anesthesiologists vs. Nurse Anesthetists

During my earliest years at the Mayo Clinic the only recognized national organization devoted to anesthesia was the International Anesthesia Research Society. It was then headed by Dr. Frank H. McMechan, who was so crippled by arthritis that he was more or less helpless,[6] but as a consequence of the great efforts of his wife, Laurette, he was able to carry on his responsibilities. He was determined that anesthetic agents would be administered only by those who held either a medical or a dental degree. This attitude caused a considerable difference of opinion among those of us who recognized the great contributions which nurses had made in administering anesthetic agents prior to the time that physicians like myself had entered the field. The late Dr. Arthur Dean Bevan, of Chicago, head of the Department of Surgery in the Rush Medical College and president of the American Medical Association in 1918 and 1919, had a novel idea which he defended stoutly: he maintained that the proper person to administer general anesthetic agents was a woman doctor of medicine.

It was apparent to me, even then, that it was expedient to use any well-trained and experienced person who was available to give anesthetic agents. As a matter of fact, in the early days after the invention of the gas machine, lay persons acting as salesmen for the manufacturing company in question administered anesthetic agents in the demonstration of their gas machines, and they were much better qualified for that purpose than anyone else at that time. As it is now, recent emphasis upon the necessity of using paramedical personnel as much as possible in the practice of clinical medicine as a means of enhancing the effectiveness of the physician only points up the wisdom of our use of nurse anesthetists in years gone by.

Section on Anesthesiology, American Medical Association

In those early years I felt as if I were garbed in Joseph's coat of many colors. I was anxious to join some organization in which a physician like myself, with my primary interest in everything pertaining to anesthesia, might take part in a relationship which would be of mutual benefit to society, to physicians and surgeons and especially to patients. I therefore applied to the American College of Surgeons, since every member of that organization had a basic concern with anesthesia. But the College refused to consider me for membership because I was not a surgeon. I then applied to the American College of Physicians, which straightaway gave me the same reception. I thus remained suspended in a medical limbo, and I often maintained that I was in fact the last person the patient ever saw between the attending physician or surgeon and the undertaker. But, since I never became known for indecision or abnegation, I set about to hot up the fire and see what rare distillation I could brew. It was evident that we in anesthesia would have to have our own working organization. For that reason, every time I passed through Chicago, which was often, I would call upon the late Dr. Olin West, secretary and general manager of the American Medical Association from 1924 to 1946, and urge him to create a section on anesthesia within the American Medical Association. As the years went by I had my way. The Section on Anesthesiology was established in 1940,[7] with the implicit understanding that I was to remain secretary until the section should have become well functioning. That I did for 17 years.

International Anesthesia Research Society

At about that time I was asked to make a decision by a friend of mine who said that as the result of a variety of circumstances he was in a position either to sustain or to destroy the old organization of anesthetists which Dr. Frank H. McMechan had largely built up and

maintained. I urged my friend to take measures which would perpetuate the society in question, saying that I thought scientific competition carried on in two organizations—the American Society of Anesthetists, Inc., as it was then known, and the older International Anesthesia Research Society—would be a good thing. I think I was justified in that opinion, particularly since in recent years Dr. T. Harry Seldon, a member of the Section of Anesthesiology of the Mayo Clinic, has helped to make the International Anesthesia Research Society very successful. He has been a member of the board of trustees of the society since 1948 and editor of its journal, *Anesthesia and Analgesia —Current Researches*, since 1954.

American Society of Anesthesiologists, Inc.

Some time in the 1930's I had lunch with Dr. Paul M. Wood, of New York City, in the course of which I told him I thought that as physicians administering anesthetic agents we ought to have a name which would distinguish us from the nurse anesthetists, who had organized the National Association of Nurse Anesthetists in 1931.* He proposed the word, "anesthesiology." I told him to look into the subject carefully, which he did. Later we discussed it again and decided that the word was valid etymologically. I said: "Let's put it to work."

Among other things, we talked about creation of a national society. It was agreed that he would try to get the New York Society of Anesthetists, which had existed since 1905, to change its name to the "American Society of Anesthetists, Inc.," which was done in 1935. It was not until 1945, however, that we were able to substitute the word, "anesthesiologists," for "anesthetists." In the meantime we had managed to establish a journal, the first issue of which appeared in July, 1940, designated by our new word, *Anesthesiology*. The title of the journal immediately established the name, "anesthesiology," in every medical library, and since custom is ineluctably more binding than fiat, the name of our journal became accepted everywhere, as did the variant, "anesthesiologist."

*This organization changed its name to the present "American Association of Nurse Anesthetists" in 1939.

American Board of Anesthesiology, Inc.

Shortly before *Anesthesiology* was founded, the various certifying boards in medicine and surgery were being formed. It seemed desirable that there be a board to certify specialists in anesthesia. Again Paul Wood and I discussed how such a board might be created. It was our conviction that we could organize a college of anesthesiologists within the American Society of Anesthetists, Inc., for the examination and certification of competent physicians engaged in the practice of anesthesia. Such was our plan at the moment, but it did not turn out that way. Before we could make much progress with plans for a college of anesthesiologists a number of persons, and especially the late Dr. Ralph Tovell, concluded an arrangement with Dr. Fred W. Rankin, at the time secretary of the Section on Surgery of the American Medical Association. A committee of representatives of the American Society of Anesthetists, Inc.; the American Society of Regional Anesthesia, Inc.; and the Section on Surgery of which Dr. Rankin was Secretary, devised a plan for bringing a certifying board in anesthesiology into existence in 1937, as an affiliate of the American Board of Surgery, Inc.[8] It became a separate entity, with the name, "American Board of Anesthesiology, Inc.," in 1941.

American College of Anesthesiologists

However, there was a place for both a college of anesthesiologists and a specialty board, since the board certified only those physicians who limited their practice entirely to anesthesiology, whereas, as we conceived a college of anesthesiologists, it would be empowered to certify a physician as competent in anesthesiology even though he spent but a part of his time in that special field. We pursued our plans, therefore, and the American College of Anesthesiologists was founded in 1947, as a part of the American Society of Anesthesiologists, Inc.

Graduate Refresher Courses

Now it was very apparent during examinations for entrance into the American College of Anesthesiologists that prospective members

were not very well informed on a good number of subjects in medicine. We saw the necessity for some means by which educational endeavors might be carried on. My ideas on the problem and its solution were very definite because I had been participating in the educational program which the American Academy of Opthalmology and Otolaryngology presented each year at annual meetings of the organization. The Academy was offering refresher courses in ophthalmology and otolaryngology which I thought were excellent.

I finally persuaded the American Society of Anesthesiologists, Inc., to pay the expenses of Dr. Stevens J. Martin, of Hartford, Connecticut, president of the Society in 1953, for a trip to Chicago so that he could meet me at one of the meetings of the American Academy of Ophthalmology and Otolaryngology. He did so, and was impressed by what he saw and heard. The next year, under his direction and mine, we began to present refresher courses in anesthesiology and allied subjects at the annual meetings of the American Society of Anesthesiologists, Inc., and my impression is that this educational program has been very successful.

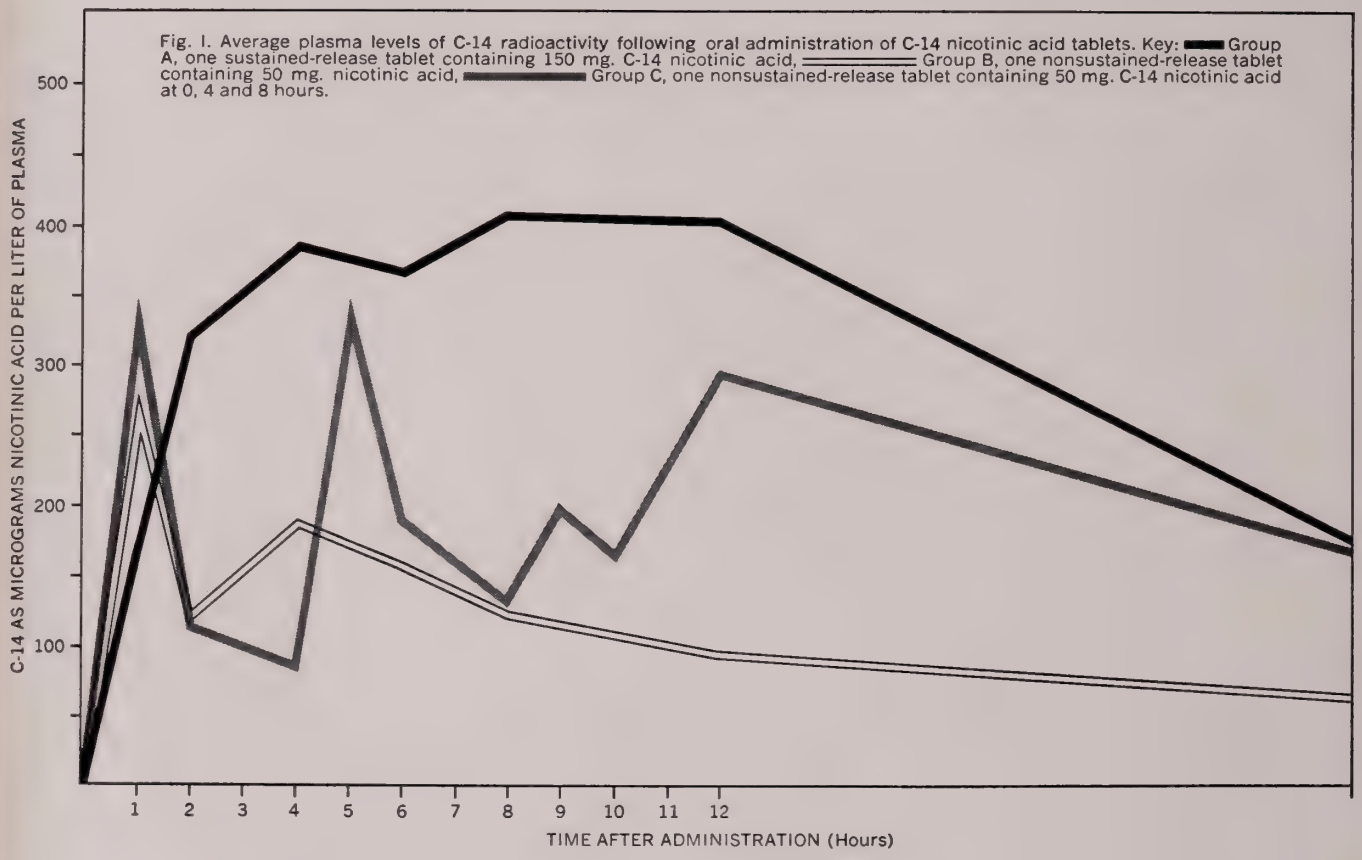
Anesthesia in Europe

In 1938 the Mayo Clinic sent me to Europe with Mrs. Lundy. I visited most of the great medical centers on the continent and in Great Britain, and what I saw there convinced me that anesthesia had made more progress in the United States than anywhere else. This was not sufficient, however, to diminish my lifelong belief that the struggle for improvement in any field must be incessant and vigorous.

Meetings of Societies

The possibilities for the acquisition of valuable knowledge by attendance at medical and scientific meetings are so great that any man privileged to make such journeys is fortunate indeed. I have calculated that the Mayo Clinic through the years allowed me to attend so many meetings and to go on so many clinical trips that the time thus spent amounted to almost three or four months in each year for 30 years. Very likely, in these times, such protracted absences from daily practice would not be tolerated; in fact they probably would not be needed today.

Special Society for Group Anesthesiology



When I contemplate the nature and functions of group experience in anesthesia as a vista encompassing more than a quarter of a century, I am impressed by the fact that the survival and flourishing of this type of group endeavor constitute the best evidence that was needed, and that, when I took up this form of practice in 1924, it was the right thing to do. The number of physicians engaged in this special field of anesthesiology is increasing constantly, and so it is indeed appropriate that such a group as this one—all members of which are interested and most of whom are involved in the group practice of anesthesiology—should be formed. Such an idea in fact was suggested to me many years ago, at a time when there were very few of us in group practice. I rejected it then on the ground that the specialty of anesthesiology ought not to be divided any more extensively than it was at that time, an era in which there were really too few of us. Now the opposite situation exists: there are so many anesthesiologists that small groups within the specialty are necessary.

In a group such as this one I think a practice once employed by the old Anesthetists' Travel Club, founded in 1929, would be desirable to use now. It was the policy of the Anesthetist's Travel Club to invite persons from any specialty to attend the meetings under some form of invitation so long as the front rows were reserved for the original members of the club. I think it would be especially interesting, for instance, to have present men who had been trained by still others who had taken their graduate training in anesthesiology at the Mayo Clinic and the Mayo Graduate School of Medicine. It should prove to be fruitful, also, to invite any who are interested in the field to be present at such meetings. To ensure honesty of purpose there should be no closed-door sessions.

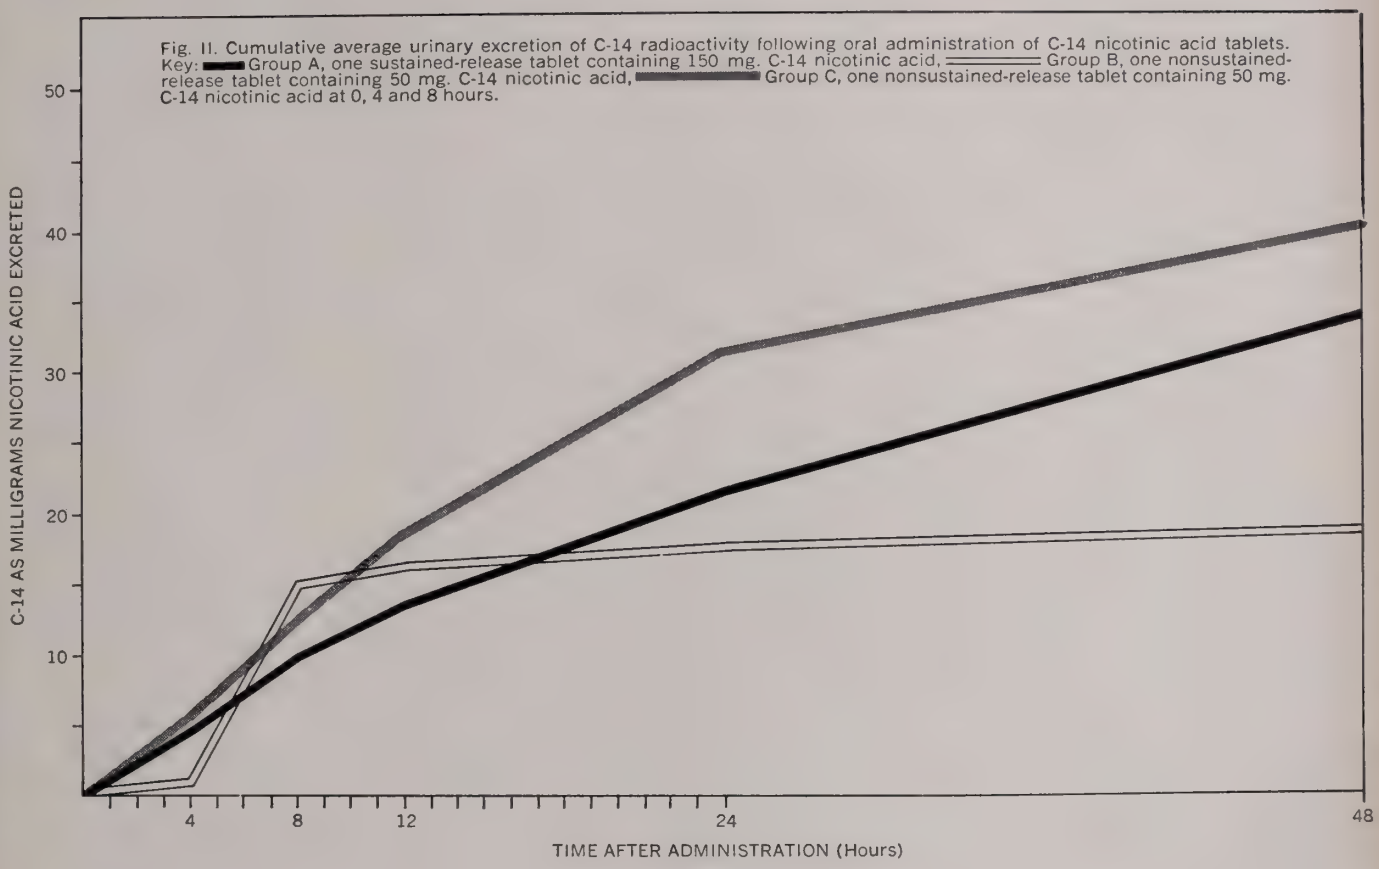
We meet people who seem to overlook and read us with a smile, but they do not tell us what they read.—Emerson

Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by absent-minded patients)



Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

aged and debilitated

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Rural Medical Scholarship Winner

As a teenager, Larry Eugene Lyon, winner of the 1967-68 Rural Medical Scholarship, had a serious nasal problem. He was referred for a delicate operation which only a few doctors in the world were qualified to perform. He remembers how lucky and how thankful he felt to have his problem corrected. While a patient he began to think of what a rewarding career he could find in medicine.

Larry is today a freshman medical student at the University of Minnesota Medical School. As the winner of the Rural Medical Scholarship, he will receive $1,000 a year for each of the four years he is in medical school, with the stipulation that he will practice medicine for five years in a rural Minnesota community approved by the Scholarship and Loans Committee immediately after internship. But this is Larry's desire. He was raised in small communities and wants to return to them to assume "what I feel is my responsibility to society and myself."

Larry is the son of Reverend D. F. Lyon and Mrs. Helen Lyon. Rev. Lyon is a Methodist minister in Luverne, Minnesota. Larry was born in Marion, Ohio, but eventually his family moved to Sleepy Eye, Minnesota. After graduating from Sleepy Eye Public High School, he attended and graduated magna cum laude from Hamline University in St. Paul. He married the former Linda Holland and they are expecting their first child this spring.

Larry is the 17th winner of the scholarship established to provide worthy and outstanding students with financial assistance and to insure a continuing supply of physicians for the non-metropolitan areas of Minnesota.

Larry E. Lyon

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

NORTHLANDS REGIONAL MEDICAL PROGRAM

REGIONAL PROGRAM FOR HEART DISEASE, CANCER AND STROKE

New Systems Are Coming in Medicine

In the last six years the following six significant national commission or committee reports suggest patterns for the future in medical education and practice.

I. *Lifetime Learning for Physicians.* This "Dryer Report" published in 1962, recommended an elaborate new system for lifetime learning of physicians in the "University Without Walls." The new coordinated system prescribed cooperative programs between physicians, teaching centers, community hospitals and the medical organization. Continuing education courses must emphasize the following criteria—personal satisfaction, freedom of choice, continuity, accessibility and convenience.

II. *The Graduate Education of Physicians.* Acclamation of this "Millis Report" compares with the epic "Flexner Report" of 1910. "Medicine exists to serve society . . . it must be responsive to the needs of the society it serves." "Physicians are the persons who best know the limitations, the possibilities and the expected directions of change in medical practice, and this fact imposes upon them the obligation of deciding how the health needs of society can best be met." The recommended new national system for control of all graduate medical education included a new medical specialist—the "Primary Physician."

III. *A National Program to Conquer Heart Disease, Cancer and Stroke.* The "DeBakey Report" published in 1964 was the forerunner of the Regional Medical Program Act of 1965. Organized medicine significantly influenced the final form of this legislation and a majority of its recommendations were adopted. This focus is on the patient. The key is local autonomous development of new cooperative arrangements between medical centers and all medical care facilities and personnel.

IV. *Health is a Community Affair.* A National Commission on Community Health Services published a comprehensive report in 1966 after four years of extensive studies. Key recommendations from these studies can be recognized in the Regional Medical Program and Comprehensive Health Planning legislation. The emphasis is on local "action-planning" by community health-planning councils, and geographic definition by "Health Services Marketing Areas."

V. *Meeting the Challenge of Family Practice.* This "Willard Report" by the AMA in 1966 recommends a new system for producing a new specialist

in medicine—the Family Practice Specialist. The family physician is the first medical contact for patients, the key to the referral process, and the integrator of health services. He will be trained to function in a new system where he can call upon appropriate specialists, sub-specialists and paramedical associates to assist him.

VI. *Health Manpower.* This 1967 report documents the needs for large increases in the numbers of almost every category of health care workers. Since an adequate increase in numbers cannot be immediately forthcoming, new systems will be required to improve utilization and effectiveness of existing health manpower.

Can there be any doubt that new systems are coming? Is there any doubt that our profession is challenged to lead in developing new systems to solve medical care and medical education problems? A skeptical "wait-and-see" philosophy will worsen the crisis and increase outside influences.

The Northlands Regional Medical Program offers an opportunity to develop new cooperative arrangements for solution of medical care and medical education problems in Minnesota. We need active participation by all Minnesota physicians.

Winston R. Miller, M.D., F.A.C.P.
Program Director

Poropathy

Arthur de Collard turned up in Richmond, Va., and persuaded the legislature in that State, in 1918, to license him to practice poropathy. Arthur claimed to be a cousin of Napoleon and a graduate of several European universities. His diplomas, he said, had all been burned, and he would not answer the simplest question on the elements of medicine and surgery. The bill defined poropathy and manipulative surgery as a new branch of therapeutics. It employs no medicine taken through the stomach and does not employ the knife. Healing and curative agencies and lotions, however, applied directly to the diseased organs and to the nerves controlling those organs, through the pores of the skin and the mucous membrane, which are opened by medical manipulation, immediately reach the disease or ailment through the eliminating organs, and by this process heal and cure most of the ills to which flesh is heir, including: internal cancer, cerebrospinal meningitis, epilepsy, tuberculosis of the joints and heart disease. This system, according to the bill, would adjust, heal and cure broken bones, sprains and dislocations. After a committee substitute for the bill and various amendments to the substitute had been rejected, the bill was passed and Arthur de Collard through it acquired the right to practice poropathy in Virginia. There are now several poropathists in the state who have taken a course under de Collard.*

Horsemint is good for wind and colic in the stomach.—Nicholas Culpeper

Physician's Diary

Dr. John H. Rosenow, a clinical instructor in surgery at the University of Minnesota Medical School, has been appointed Senior Associate Editor of *Modern Medicine.*

* * *

St. Mary's Hospital will have a Extended Care Center by the spring of this year, and **Eitel Hospital** has a new east wing and major renovation work in the 60-year-old south wing.

* * *

Dr. C. A. Tietz of the Lenont-Peterson Clinic in Virginia was recently certified as a diplomate of the American Board of Obstetrics and Gynecology, and **Dr. Patrick Bosley,** Balaton, has been elected to active membership in the American Academy of General Practice.

* * *

Dr. Clarence J. Rowe, St. Paul, has been appointed chairman of the Joint Committee on Mental Health in Industry of the American Medical Association.

* * *

Dr. Joseph H. Pratt, head of a section of surgery in the Mayo Clinic, was elected president of the Society of Pelvic Surgeons at their annual meeting.

* * *

Dr. George B. Logan, Rochester, has been reappointed principal representative of the American Academy of Pediatrics of the American Medical Association's Interspecialty Committee for 1968.

* * *

Dr. Ramon Mendiola has been named Chief of Staff of the Waconia Ridgeview Hospital, and **Dr. Robert T. Hilker** has been elected president and Chief of Staff of the medical staff of the Owatonna City Hospital.

* * *

Dr. Walter Dowswell has retired after twenty-five years of dedicated service in the practice of medicine in Kerkhoven.

* * *

Dr. William H. Rock is the newly elected Chief of the Medical Staff of Mercy Hospital in Anoka, and **Dr. L. G. Reichelt** was elected Chief of Staff of the Wesley Hospital Medical Staff of Wadena.

Dr. Herman E. Drill, Hopkins, has been appointed to a one-year term on the Committee on Indian Health of the American Academy of General Practice.

* * *

Dr. W. Albert Sullivan, Jr., Minneapolis, has been reappointed a member of the Committee on Continuing Medical Education of the American Medical Association.

* * *

Dr. Charles Field, has been named president-elect of the medical staff of the Olmsted Community Hospital. **Dr. Frank Sander** will assume presidency of the hospital.

* * *

Dr. O. E. Winger is the newly elected president of Pierz's St. Gabriel's Hospital Medical Staff, and **Dr. Carl E. Christenson** is the new president of Ortonville's Municipal Hospital Medical Staff.

* * *

Dr. Victor K. Funk of Minnetonka, former Hennepin County Chest Clinic director, is the recipient of the County's Outstanding Community Service Award.

* * *

Dr. Harry J. Smith of Lake Crystal has been elected to the medical staff of Immanuel Hospital Medical Staff in Mankato, and **Dr. Clarence Everhart** has been named pathologist for Glenwood Hills Hospital in Robbinsdale.

* * *

Dr. Earl Dagg, Thief River Falls, is the newly elected president of the Red River Valley Medical Society. Other officers include: **Dr. Owen Holm,** Crookston, vice president; **Dr. H. D. Clapp,** Crookston, secretary-treasurer.

* * *

Dr. Ralph Knight of Minneapolis was one of four men invited to participate in the Wood Library-Museum's "Distinguished Visitors Week," in April. He joined discussions of current Museum projects and helped identify some of the hundreds of pieces of antique equipment which have been donated to the Museum.

The relief received from the first Trocinate 400 mg. tablet is so prompt that the discomfort of diarrhea ceases to be a bother. May be repeated every four hours.

Upon request, a supply of Trocinate 400 mg. with literature will be sent to physicians for their personal use.

mudrane®

for

- EMPHYSEMA
- ASTHMA
- CHRONIC BRONCHITIS
- BRONCHIECTASIS

Each tablet contains:

Potassium Iodide	195 mg.
Aminophylline	130 mg.
Phenobarbital, Caution: May be habit forming...	21 mg.
Ephedrine HCl	16 mg.

FEDERAL LAW PROHIBITS
DISPENSING WITHOUT PRESCRIPTION

Precautions: Usual for aminophylline-ephedrine-phenobarbital. Iodides may cause nausea, long use may cause goiter. Discontinue if symptoms of iodism develop.

Iodide contraindications: tuberculosis, pregnancy.

DOSAGE

One tablet, with full glass of water, 3 or 4 times daily.

Dispensed in bottles of 100 and 1000 tablets.

MUDRANE GG—Formula, dosage and package identical to Mudrane—*except*—100 mg. glyceryl guaiacolate replaces the potassium iodide. The value of Mudrane cannot be enjoyed by a small group in which K.I. is contraindicated. Mudrane GG is prepared for this group.

MUDRANE GG ELIXIR—Four 5 cc teaspoonfuls is equivalent to one Mudrane GG tablet. Dosage adjusted to age and weight of child. Mudrane GG Elixir is for pediatric patients and those who think they cannot swallow tablets. Dispensed in pint and half gallon bottles.

Minnesota Medicine at a Glance

Hydrocephalus—*Long et al.* Page 761

An extensive evaluation of the various ways hydrocephalus has been managed at the University of Minnesota Medical Center since 1938 is presented. Types of operative procedures, their complications and long-term results are compared. The ventriculo-atrial shunt is the operation of choice in the majority of cases of hydrocephalus.

Bilateral Spontaneous Massive Perirenal Hemorrhage—*Gambill et al.* Page 767

Perirenal bleeding in periarteritis is rare and bilateral perirenal hematomas rank as medical curiosities. The authors found four in the world literature and report the fifth case. The right-sided hemorrhage occurred five days after liver biopsy; the left two weeks later. The patient survived one month.

Coarctation of the Aorta in Veterans—*Beard and Sako* Page 775

A 19-year experience in dealing with coarctation of thoracic aorta is reviewed. Diagnostic features and treatment are considered. It is of considerable interest that a number of these patients had escaped detection and precise diagnosis, despite previous relatively complete physical examinations. A number had been considered malingerers.

Neointimae—*Shimamura et al.* Page 779

With the abundant developments of vascular surgery it is interesting to learn that a prosthetic aorta can develop for all practical purposes a serviceable intima within its lumen.

What's New?

Contraception without cerebration! Syntex announces its pill-a-day oral contraceptive, Noriday. This innovation consists of 21 white tablets containing 1 mg. of norethindrone and 0.05 mg. of mestranol plus seven orange tablets containing inert ingredients. This product is designed to avoid missed doses and miscalculations on the part of the woman taking contraceptive medication.

Lederle Laboratories announces a new anti-tuberculosis drug, Myambutol ethambutol. The drug is reported to be effective in cases of tuberculosis with drug-resistant organisms. Human studies with the drug have now been conducted for six years and one of the side effects associated with the drug has been the occasional reduction in visual acuity which is apparently reversible when the drug is discontinued. Myambutol appears to be highly specific against the tubercle bacillus, has a low incidence of side reaction and slow emergence of resistant strains. It has been used both alone and in combination with isoniazid or with streptomycin and isoniazid.

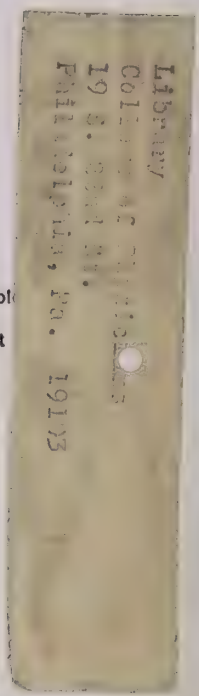
Unless each claim has a valid signature the claim is void and must be returned to you.

BLUE SHIELD
OF MINNESOTA

the "Librium® effect"
(chlordiazepoxide HCl)

For years, physicians have valued Librium (chlordiazepoxide HCl) capsules for their reliable calming effect.



(in capsules)

Now, the same dependable antianxiety effect can be obtained with convenient tablets—Libritabs (chlordiazepoxide).

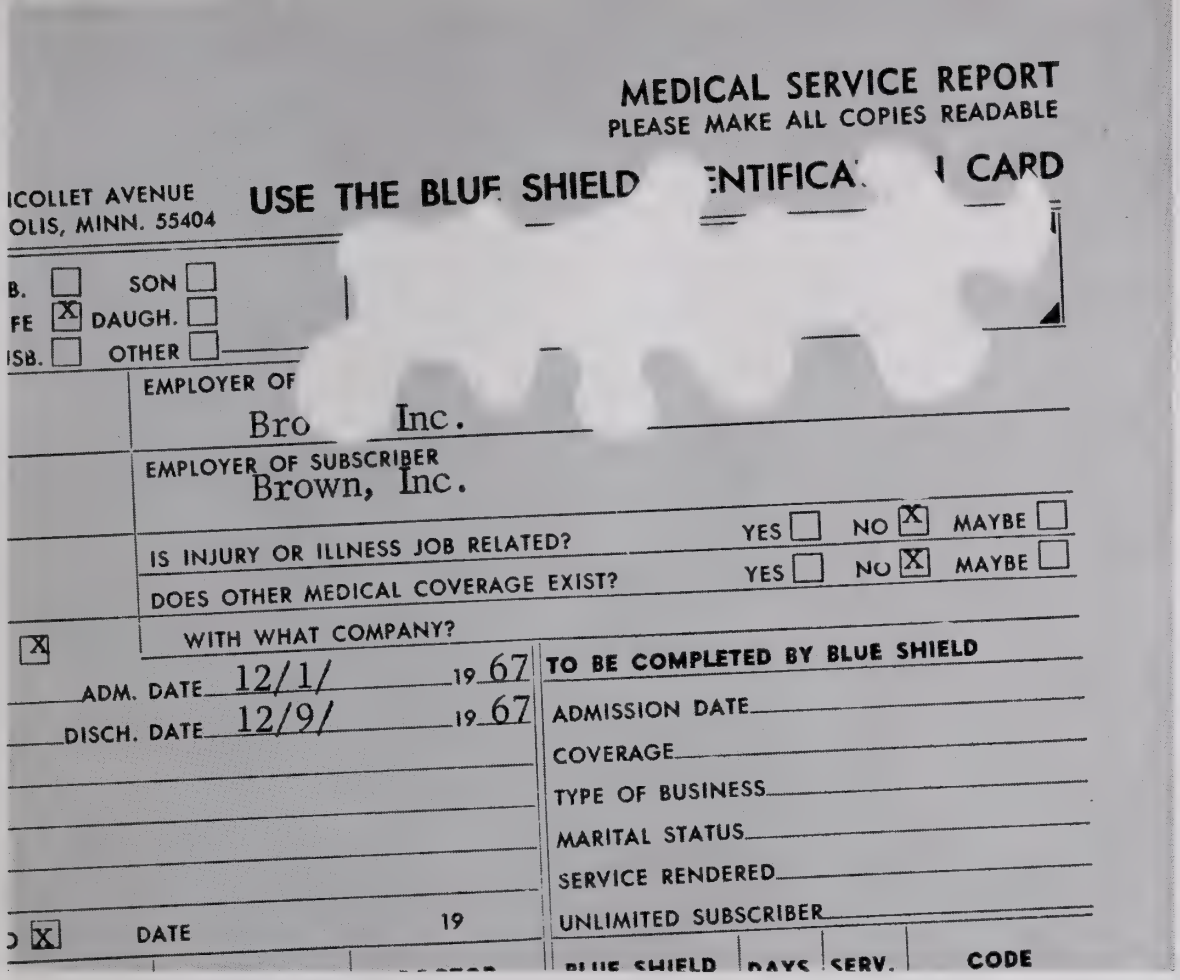
(in Libritabs™)
(chlordiazepoxide)

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.



Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver-function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral*—Adults: Mild and moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d. (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) Capsules, 5 mg, 10 mg and 25 mg—bottles of 50. Libritabs™ (chlordiazepoxide) Tablets, 5 mg, 10 mg and 25 mg—bottles of 100. With respect to clinical activity, capsules and tablets are indistinguishable.

PATIENT
Wn,

BLUE SHIELD OF MINNESOTA

Open-eyed nights

Too tense to sleep...too tired to get up. **Early to bed, late to rise, and not much sleep at that, the patient with severe psychic tension is understandably tired. His tensions and overreactions to the day's stresses may interfere with proper sleep, and his inability to face the day's activities can produce an ever-worsening pattern. By relieving psychic tension, Valium® (diazepam) facilitates sleep, particularly with an h.s. dose. In many patients, the usefulness of Valium has been demonstrated in relieving psychic tension alone or with secondary depressive symptoms. Valium is generally well tolerated and, with proper maintenance dosage, usually does not unduly impair mental acuity or ability.**

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in: skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders; athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindications: Known hypersensitivity to drug; children under 6 months of age; acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in treatment of psychotic patients, and should not be employed in lieu of appropriate treatment. As with most CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increase in dosage of standard anticonvulsant medication; abrupt withdrawal in such cases may also be associated with temporary increase in frequency and/or severity of seizures. Advise patients against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance. Keep addiction-prone individuals (such as drug addicts or alcoholics) under careful surveillance because of their predisposition to habituation and dependence. Use of any drug in pregnancy, lactation or in women of childbearing age requires that potential benefit be weighed against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, carefully consider individual pharmacologic effects—particularly with known compounds which may potentiate action of Valium (diazepam), such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. Employ usual precautions in the severely depressed or in those with latent depression; suicidal tendencies may be present and protective measures necessary. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation (initially 2 to 2½ mg once or twice daily, increasing gradually as needed or tolerated).

Adverse Reactions: Side effects most commonly reported: drowsiness, fatigue and ataxia. Infrequently encountered: confusion, constipation, depression, diplopia, dysarthria, headache, hypotension, incontinence, jaundice, changes in libido, nausea, changes in salivation, skin rash, slurred speech, tremor, urinary retention, vertigo and blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances and stimulation have been reported; should these occur, use of the drug should be discontinued. Because of isolated reports of neutropenia and jaundice, periodic blood counts and liver function tests are advisable during long-term therapy. Minor changes in EEG patterns (low-voltage fast activity) observed during and after therapy and are of no known significance.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 50, 100 and 500.

JULY, 1968

He is elderly, he is on corticosteroids, when he needs an antibiotic he may be a candidate for

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg and Nystatin 500,000 units CAPSULE-SHAPED TABLETS Lederle

b.i.d.

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken.

In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given the drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, food and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

BSP® DISPOSABLE UNIT

HW&D BRAND OF SODIUM SULFOBROMOPHTHALEIN INJECTION, USP

(50 mg. per ml.)

BSP®

BROMSULPHALEIN®

IN A COMPLETE,

STERILE,

DISPOSABLE,

& ECONOMICAL

PATIENT-UNIT.

BSP, one of the more valuable single laboratory procedures for determining hepatic function, is now packaged in a complete individual patient-unit.

Each BSP Disposable Unit contains a sterile syringe with the 5 mg./kg. BSP dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of terminally sterilized Bromsulphalein solution.

This all-inclusive disposable put-up lessens the chance of cross-infection and saves time and labor— the most costly commodities.

FACT & LEGEND

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety... helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

No injection after all!

This penicillin produces high, fast levels—orally.

Pen•Vee® K is usually so rapidly and completely absorbed that therapeutic penicillin levels are attained within 15 to 30 minutes. Thus it can often obviate the need for penicillin injections. The higher serum levels produced generally last longer than with those of oral penicillin G.

Indications: Infections susceptible to oral penicillin G: prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.
Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.
Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.
Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.
Adverse Reactions: (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").
Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

President's Letter

Anesthesia in Minnesota

ATTENTION HAS BEEN focused in the past year on the practice of anesthesiology in the hospitals of Minnesota. What began as an inquiry into the qualifications of those administering general anesthetics has progressed to several active plans for continuing education of physicians and nurses. Standards and guidelines for anesthesia departments, to improve the quality and safety of anesthesia, should soon evolve.

Early in 1967 the Minnesota Society of Anesthesiologists submitted a resolution to the Minnesota State Medical Association requesting that it conduct such studies as were necessary to establish minimal standards of training and competence for persons administering anesthetics. The House of Delegates of the Minnesota State Medical Association passed the resolution and designated its Committee on Anesthesia to carry out the fact-finding survey. A complete survey of Minnesota hospitals was not needed because recent information was already available. The State Board of Health had done studies in 1958 and in 1966, in relation to licensing of hospitals, on the training qualifications of those giving anesthetics.

In brief, by 1966 there had been much improvement in the qualifications and training of those giving anesthetics. There are 432 certified registered nurse anesthetists employed in 172 of the 184 hospitals in Minnesota. There are approximately 140 trained anesthesiologists in the state. Two hospitals use only anesthesiologists, 112 have only certified registered nurse anesthetists, and 45 have both anesthesiologists and anesthetists. In the state are 20 smaller hospitals in which some anesthetics are not given by full-time physician-specialists or certified registered nurse anesthetists. In five of these, anesthetics are given by general practitioners; in four others, anesthetists are registered nurses with formal anesthesiology training but are not certified. Five hospitals use nurses with less than complete anesthetist training and six others use "job-trained" anesthetists. In all, seven persons with less than full nurse anesthetist training and 10 with job training are administering anesthetics.

The following recommendation was approved by the Minnesota State Medical Association in March 1968: That an Anesthesia Advisory Committee to the State Board of Health be formed, to draw up a voluntary set of standards and guidelines for departments of anesthesia in Minnesota. Representatives from the Minnesota State Medical Association, Minnesota Hospital Association, Minnesota Nurse Anesthetists' Association, and Minnesota Society of Anesthesiologists will be included. A cooperative endeavor by all these organizations to develop regional educational programs and equipment standards should do a great deal to improve safety in anesthesia.

Mitral Valve Reconstruction

JOSEPH C. KISER, M.D.
THEODORE A. PETERSON, M.D.
FRANK E. JOHNSON, M.D.
Minneapolis, Minnesota

In spite of recent advances in prosthetic valve design and construction, arterial embolization and mechanical dysfunction continue to be serious problems. In the mitral position, the hazard of embolization seems to be particularly severe, even with optimal anticoagulant control.[1] Perhaps more consideration should be given to repair of the existing valve when conditions warrant. In the absence of calcification or extensive loss of tissue substance of the anterior mitral leaflet, application of proven repair techniques may yield satisfactory results.

The following five case reports are examples of severe mitral valve disease treated by various reconstruction techniques. In three of these patients, multiple valve disease was present. All five patients are living and have shown early evidence of improvement.

Case Reports

Case No. 1:

A 65-year-old female was a functional class III-c, moderately cachectic with known atrial fibrillation of ten years duration. Grade IV apical holosystolic murmur and grade II apical diastolic murmur. No ascites, hepatomegaly, or peripheral edema.

Chest X-ray and Cardiac Fluoroscopy

Cardiomegaly with double contour of left atrial enlargement, minimal mitral valve calcification.

Electrocardiogram

Atrial fibrillation, right axis deviation with ST and T-wave changes consistent with digitalis effect.

Cardiac Catheterization

Pulmonary artery pressure 60/25, wedge 35 (mean), cardiac output 1.5 L/min/m^2 (index). No aortic valve gradient. Aortic root injection revealed no aortic valve incompetence. Left ventricular injection demonstrated marked mitral regurgitation.

Surgery August 8, 1967

Heart enlarged in all chambers. Left atrium markedly enlarged. Strong thrill over the left atrium posteriorly. No thrill palpable over the right atrium. The patient's condition deteriorated with anesthesia, so that pressure measurements could not be obtained. Extracorporeal circulation was instituted and the mitral valve was exposed from the right side. There was some calcification at the posteromedial commissure and a fixed orifice measuring about 2.0 × 1.5 cm. The commissural fusion was split to the annulus in both directions. There was marked subvalvular fusion of the chordae tendinae.

The anterior papillary muscle was incised longitudinally between the chordae and a posteromedial annuloplasty was performed. There was no systolic thrill over the left atrium at the conclusion of the procedure.

The immediate postoperative condition was satisfactory without any tendency toward the "low output syndrome." Her convalescence was slow but uncomplicated. Fluid retention did not occur. She was discharged from the hospital on the twentieth postoperative day.

Case No. 2

A 52-year-old female was a functional class III with bilateral pleural effusions. Recent onset of atrial fibrillation. Grade IV systolic ejection murmur at the left sternal border, radiating into the base of the neck. Grade III holosystolic apical murmur radiating toward the axilla and audible in the back. Grade II blowing diastolic murmur heard along the left sternal border. No ascites, hepatomegaly or peripheral edema.

Chest X-ray and Cardiac Fluoroscopy

Cardiomegaly with evidence of left atrial enlargement. No valvular calcification seen.

Electrocardiogram

Atrial fibrillation, digitalis effect.

Cardiac Catheterization

Confirmed the clinical diagnosis of severe aortic valve disease and marked mitral valve incompetence.

Surgery September 6, 1967

Heart enlarged in all chambers. No thrill over the right atrium and no definite thrill over the left atrium. The aortic valve was found to be severely diseased and was replaced with a #3 Cutter prosthesis. The mitral valve was predominantly stenotic with a central orifice measuring 7 to 8 mm. in diameter. There was minimal calcification in the posteromedial commissure. The commissures were split to the annulus in both directions and a posteromedial annuloplasty was performed. The remainder of the procedure was concluded in a routine fashion.

The postoperative course was uncomplicated. At the time of dismissal from the hospital, there was a grade I apical systolic murmur.

Case No. 3

A 36-year-old female with recurrent mitral stenosis had had a closed mitral commissurotomy performed eight years prior to this admission. Functional class II-b with increasing dyspnea on exertion in the past year and hemoptysis two months prior to this admission. Loud apical diastolic rumble with an opening snap audible.

Chest X-ray and Cardiac Fluoroscopy

Mitral configuration. No evidence of valvular calcification.

Electrocardiogram

Sinus rhythm, right axis deviation.

Surgery January 17, 1968

Dense adhesions obliterating the pericardial space. Moderately enlarged left atrium. Diastolic thrill palpable over the left ventricle. No systolic thrill palpable over the left atrium. Extracorporeal circulation was instituted and the mitral valve was exposed from the right side. The valve was severely stenotic with a central orifice that measured about 7 mm. in diameter. There was no valvular calcification. The dilator was introduced and with the first attempt, the anterolateral commissure opened completely, but a severe rent occurred posteriorly and medially. This commissure was then incised with a knife and a posteromedial annuloplasty performed. At the conclusion, the diastolic thrill was gone and there was no systolic thrill palpable over the left atrium.

The postoperative course was uncomplicated and there were no murmurs audible at the time of dismissal from the hospital.

Case No. 4

A 71-year-old female, functional class IV, had had rheumatic fever at age 15 years with symptoms of dyspnea on exertion being prominent at age 55 years. She had taken digitalis for fifteen years. Progressively more severe dyspnea during the past four years and currently dyspneic at rest. Marked neck vein distention in the sitting position. Previous history suggestive of ascites. Grade IV holosystolic murmur at the apex, radiating to the axilla and audible in the back. Grade III systolic murmur along the lower right sternal border which seemed louder with inspiration. Liver enlarged and pulsatile. No ascites or peripheral edema evident.

Chest X-ray and Cardiac Fluoroscopy

Marked enlargement of all chambers with considerable enlargement of the right atrium. No valvular calcification seen.

Electrocardiogram

Atrial fibrillation.

Cardiac Catheterization

Confirmed the clinical diagnosis of severe mitral incompetence and ruled out aortic valve disease. Right atrial pressure 18/8 Hg with activity of the catheter in the right ventricle suggesting marked tricuspid incompetence. Severe pulmonary hypertension with a pulmonary artery pressure of 110/38. Unable to obtain a wedge pressure.

Surgery March 14, 1968

All chambers enlarged with marked enlargement of the right atrium. Strong thrill palpable over the right atrium and posteriorly over the left atrium. Unable to obtain pressure measurements. Extracorporeal circulation was established and the mitral valve was exposed from the right side. There was minimal calcification in the commissures near the annulus. There was a fixed central orifice measuring approximately 2.0 × 1.0 cm. Both commissures were split to the annulus. There seemed to be adequate substance to the anterior leaflet, although the edge was rolled and there was moderate chordal thickening and fusion. A posteromedial annuloplasty was performed. The tricuspid valve was examined through a separate incision in the right atrium. There did not appear to be organic disease present. A tricuspid annuloplasty was performed by placing figure-of-eight stitches in the annulus between the anterior and septal leaflets. At the conclusion of the procedure, there was no palpable thrill over the left atrium, although there remained a thrill over the right atrium.

Her convalescence was prolonged, but without specific

complication. At the time of discharge, twenty-two days after surgery, there remained a prominent systolic murmur heard over much of the precordium, but not radiating to the axilla or to the back.

Case No. 5

A 58-year-old male, functional class III with progressive deterioration in the past two years, was admitted in congestive heart failure. With appropriate diuretics, his weight dropped from 162 pounds to 147 pounds. Marked cardiomegaly with a hyperactive apical impulse in the seventh left interspace at the anterior axillary line. Grade V apical holosystolic murmur and a harsh grade IV systolic murmur in the aortic area. Soft grade II diastolic blowing along the left sternal border. Liver slightly enlarged. No peripheral edema or ascites evident.

Chest X-ray and Cardiac Fluoroscopy

Marked cardiomegaly with evidence of left atrial enlargement, moderate calcification in aortic and mitral valve region.

Electrocardiogram

Sinus rhythm, left ventricular hypertrophy.

Cardiac Catheterization

Confirmed the clinical findings of severe mitral incompetence and marked aortic stenosis and incompetence.

Surgery March 21, 1968

Heart markedly enlarged in all chambers. Strong systolic thrill over the left atrium posteriorly and a moderate systolic and diastolic thrill over the aortic root. Right atrial pressure 10-12, left atrial pressure 28-30. Right ventricular pressure 30/2, left ventricular pressure 75/4, aortic pressure 75/25. Extracorporeal circulation was instituted and coronary perfusion was maintained throughout the procedure. The mitral valve was exposed from the right and found to contain only minimal calcification. The posteromedial commissure was partially fused and there were several ruptured chordae along the posterior leaflet. Both commissures were completely opened by sharp dissection. The ruptured chordae were repaired and a posteromedial annuloplasty was performed. The aortic valve was replaced with a #4 Cutter prosthesis.

His postoperative course was complicated by a right hemothorax requiring thoracentesis. He was dismissed on the seventeenth postoperative day. There was a grade II systolic murmur at the apex at the time of discharge which has since diminished.

Discussion

Mitral valve reconstruction was widely employed in the early days of open heart surgery. More recently, the major emphasis has been on valve replacement with prostheses of varying design and composition. In spite of the predictable hemodynamic results that can be anticipated with these prostheses, major problems still need to be overcome. Reported mortality rate figures for mitral valve replacement still are in the range of 14%-20% with the "low output syndrome" accounting for a large percentage of these deaths. Accumulated data[1] indicates that perhaps as many as 50% of patients may experience systemic embolism within thirty-six months after mitral valve replacement with the standard Starr-Edwards prosthesis. Although the early reports with cloth-covered valves have been enthusiastic, the effectiveness of this innovation is yet to be proved. Valve ring detachment from the mitral annulus, ball variance, and bacterial endocarditis also occur.

Mitral valve reconstruction in many instances can produce satisfactory results. In the absence of heavy calcification or deficient tissue in the anterior leaflet, reconstruction may be preferable to replacement. Reliable techniques that can be employed include sharp division of commissural fusion, posteromedial annuloplasty, repair of ruptured chordae, direct suture of tears or perforations, and mobilization of subvalvular fused chordae by longitudinal incision of the papillary muscles. The hemodynamic improvement gained may be difficult to assess at the time of surgery, but one may be fairly certain that significant improvement has been obtained if the systolic thrill of incompetence over the left atrium is abolished. Rarely is the murmur of mitral insufficiency completely eliminated by these techniques. However, with time, the murmur does not often increase in intensity.

Patients who have had successful mitral valve reconstruction do not require postoperative anticoagulation routinely, and systemic embolism is uncommon. Uncertain as we are regarding the etiology of the "low output syndrome," it does not often accompany mitral valve reconstruction. Recognizing the relatively rare incidence of this latter complication after mitral valve reconstruction, one might anticipate significant reduction in the operative mortality for mitral valve disease if the patients are properly selected and the techniques appropriately applied.

Our group of patients is small in number and the followup is short. There was one postoperative complication—a hemothorax requiring aspiration. Three of these mitral reconstructions were performed on patients under-

going surgery for multiple valve disease. Those patients who required concomitant aortic valve replacement have been maintained on anticoagulants. The "low output syndrome" did not occur and none of them required assisted ventilation during the postoperative period. Three of these five patients have a residual apical systolic murmur. There were no operative deaths.

Summary

1. In the absence of heavy calcification or severely deficient valve substance in the anterior leaflet, mitral valve reconstruction can provide satisfactory results.

2. The risk of postoperative arterial embolism is reduced.

3. This procedure can be accomplished with low operative mortality.

President's Letter **(Continued from Page 893)**

The Minnesota Society of Anesthesiologists believes that, while the other organizations are necessary to the success of the effort, it must assume the primary responsibility and leadership in the attempt to ensure good anesthesiology practice in this state. The fact is that there will not be an anesthesiologist at the head of every operating table in the foreseeable future. Thus, it behooves us to be teaching, helping, and even being responsible for those who are giving anesthetics. Our Society has an enthusiastic Committee on Education, with Dr. Van S. Lawrence as chairman. They are working on continuing education at the anesthetist level, with good cooperation from the Department of Health and the Nurse Anesthetists' Association. Our Society has a Speakers Bureau, with Doctors J. J. Buckley and J. T. Martin as chairmen. They offer to provide speakers on anesthesiology and related subjects to any county society or hospital staff, without cost.

These are our aims and activities; we invite your ideas and ask your cooperation for their success.

Emerson A. Moffitt, M.D.
President
Minnesota Society of Anesthesiologists

Abdominal Muscle Deficiency Syndrome

This syndrome consists of (1) partial or complete absence of abdominal musculature; (2) hydroureter, hydronephrosis, and megabladder; (3) undescended testes in males; and (4) malrotation of the intestine. Fröhlich described the first case in 1839. Fifty-eight cases have been reported to date (Mathieu *et al.*), only four of which were females.

Deficiency or absence of the abdominal muscles includes the lateral groups, the transversus, and the obliques. The recti are often present. Symptoms more often pertain to the genitourinary tract or to one of the other numerous congenital abnormalities. These include pigeon breast deformity, spina bifida with myelomeningocele, hydrocephalus, congenital bladder neck obstruction, bilateral hydroureter, urachus,* and perhaps talipes. The clinical course is often complicated by episodes of infections that require antibiotics and possible surgery. Many of these patients have a low intelligence quotient and require chronic institutional care.

The Marinesco-Sjögren Syndrome*

Hereditary Cerebello-Lental Degeneration with Mental Retardation

MILTON ALTER, M.D., Ph.D.†
WILLIAM KENNEDY, M.S., M.D.‡
Minneapolis, Minnesota

A FAMILIAL SYNDROME characterized by cerebellar ataxia, cataracts, and mental retardation was described in 1931 by Marinesco et al.[1] Subsequently, Sjögren[2] showed that the disorder is inherited as a recessive trait. In 1962 a review[3] of the literature disclosed less than forty published cases. We have recently encountered an additional case and have had an opportunity to reevaluate the variety of clinical and pathological features found in this disorder. We were able to document an abnormality of skeletal muscle. The rarity of the syndrome prompted us to report our observations.

Case Report

A nineteen-year-old boy was admitted to the University of Minnesota Hospitals for evaluation of an unsteadiness which made walking extremely difficult. He had been born after a full-term pregnancy and had weighed eight pounds at birth. Although delivery required forceps, there were no neonatal complications and the infant appeared healthy.

Retarded Rate of Development

By four to five months of age, it was recognized that his rate of development was slow. He appeared weak and did not hold up his head well. He was a year old before he reached for objects. By two years of age, he began to feed himself. Although he was toilet-trained and could say some words by two years, he did not stand alone until three years of age. He was not able to walk until age twelve. Prior to this, he moved about by inching along on his buttocks. After age twelve, he could walk if assisted. He was nineteen years old before he could walk without support, but even then his gait was unsteady.

Bilateral cataracts were removed at age three. Speech was never clear. Intelligence was estimated to be at the upper end of the defective range, and he had to attend special classes in school. His disposition was pleasant and he posed no behavioral problems.

Fig. 1—Note residual cataract, protuberant ears, and underdeveloped mandible. (Patient's permission given to reproduce figure.)

Fig. 2—The patient has a thin, lanky build, full breasts, normal phallus and pes planus. Muscle development is poor.

Family History

The patient's mother and an older sister were healthy. The father had had a successful resection of a bronchogenic carcinoma, but he died of a cerebrovascular accident at age 65. Both parents were of Norwegian descent but denied any consanguinity.* The maternal grandmother had cataracts in old age. The family history failed to suggest visual disturbances, weakness, unsteadiness, muscle wasting, baldness, stiff muscles, endocrine disturbance, or mental retardation in other members.

General Examination

The patient (Figures 1, 2, and 3) was cooperative and pleasant when first examined by the authors in 1964. His height was 5 feet, 6 inches (1.65 meters), and his skull circumference 21 inches (53.3 cm). His hair was normal. His breasts were rather large but true gynecomastia was not present. Abnormalities included prominent ears, a recessed mandible, long neck, high arched palate, absent upper right lateral incisor, absent left optic lens, residual cataract on the right, and "pigeon breast" deformity of the sternum. The heart, lungs, and abdomen were normal. The pubic hair showed a female configuration. The testes were small and soft. The phallus was normal. Other skeletal anomalies were a lumbar lordosis, a wide-flared pelvis, bilateral pes planus with short third, fourth and fifth toes, incurved third toe and short fifth fingers of both hands.

Dermal Pattern

Dermatoglyphic analysis showed ulnar loops on nine fingers. A radial loop was present on the left middle finger, an unusual site for this pattern. The total finger ridge count was a low 58. The atd angles, interdigital patterns, hypothenar, thenar, hallucal and great toe patterns were unremarkable. The palmar crease pattern was normal. Dermatoglyphics have not previously been reported in the Marinesco-Sjögren syndrome; consequently it is not known whether a low finger ridge count and an unusually placed radial loop are characteristic of this disorder.

Neurological Findings

Examination of cranial nerves showed intact olfaction.* Visual fields and the left optic fundus were normal; the right fundus could not be visualized. There was some limitation of ocular movement on lateral gaze and on convergence, but movements were conjugate.* Fine horizontal nystagmus was noted on lateral gaze and, occasionally, vertical nystagmus was elicited. The left pupil was slightly larger than the right; both pupils reacted normally to light. There was slight weakness of the masseter and temporalis muscles and their bulk was decreased bilaterally. Slight weakness of facial muscles was evidenced by the inability to close the eyelids tightly. Hearing was good. There was marked dysarthria, the speech resembling that of a young child who substitutes sounds and abbreviates syllables. The voice had an explosive quality. The tongue protruded in the midline,

*See Test Your Word Score Page 937.

but rapid alternating side-to-side and front-to-back movements of the tongue were not well performed.

Motor strength and bulk were decreased in all extremities, more proximally than distally. The grip was also weak. There was no evidence of myotonic phenomena. Fasciculations were not seen. The tendon reflexes were difficult to elicit but symmetrical. Abdominal reflexes were absent bilaterally. The Babinski response could not be elicited. A sucking response was present.

Coordination was markedly impaired. A gross intention tremor was elicited on finger-to-nose and heel-to-knee testing. He sat with minimal difficulty, but was unable to stand without support. The gait was wide-based and staggering. Balance while standing with eyes closed or open was equally poor. Sensation was normal.

Laboratory Data

The hemogram and urinalysis were normal. Results of other laboratory tests were: negative Kline test, blood urea nitrogen 14 units, calcium 9.2 mg. percent, phosphorus 4.0 mg. percent, two-hour fasting blood sugar 67 mg. percent, alkaline phosphatase 9 King-Armstrong units, serum lactic acid dehydrogenase 366 I.U., creatine phosphokinase 18.9 units (normal is 1 to 11 units), protein-bound iodine 5.9 μg percent, 17-ketosteroids 11.7 and 17-hydrosteroids 6.4 mg. both per 24 hours, serum creatine 0.6 mg. percent and urine creatine 0.91 gm. both per 24 hours, and standard creatinine clearance 170 gm. per 24 hours. Amino acid chromatography revealed an alpha-amino nitrogen excretion of 202 mg. per 900 cc. which is at the upper limit of normal. However, the relative excretion of alanine was moderately decreased.

X-Ray Changes

A roentgenogram of the skull was normal. The mandible was small in relation to the facial bones. An overbite was evident. Spine x-rays showed asymmetrical development of the body of C5, and juvenile epiphysitis involved T4 through T10 with resultant dorsal kyphosis. The medial end of the clavicles had an abnormal shape. Several ribs had a spindle-like appearance. The superior and inferior rami of the symphysis pubis were tapered. The tibiae showed slight depression of the medial plateau and both fibulae had a spindle shape. Hand x-rays were interpreted as normal, but the feet showed incurving of the third metatarsal and shortening of the fourth metatarsal bones bilaterally.

Nerve Conduction and Electromyography

Because of the poor muscle development, electrodiagnostic studies were obtained. These demonstrated normal motor conduction velocities for the right median (53 meters per second), right ulnar (57 meters per second) and right peroneal nerves (53 meters per second).

Concentric needle electrode examination of proximal and distal muscles of all extremities revealed normal insertion and resting potentials except in the left tibialis anterior where occasional fibrillation potentials firing at a low frequency were observed.

Fig. 3—Side view showing long neck, tendency to carry head forward, lumbar lordosis and poor muscle bulk.

Fig. 4—The pes planus and shortened third, fourth and fifth toes are evident.

During voluntary contraction, most motor unit action potentials were of low voltage (100-200 mv), polyphasic, and of normal duration. A few were of very short duration (1-2 msec.). The electromyogram was interpreted as being indicative of a myopathic process.

Muscle biopsies were obtained from the right biceps and left anterior tibial muscles, both of which showed a greater than normal variation in fiber size plus increased endomyseal fibrosis and fat. The muscle was considered to be abnormal but the findings were not specific. Electron microscopic studies of this muscle by Dr. E. Benson showed no abnormalities.

Discussion

Since the literature on this disorder was reviewed in 1962,[3] several additional case reports of the Marinesco-Sjögren syndrome have been published, and some reports not included in that review have been found. This new material is summarized below.

Characteristic Case Histories

Moravczik's[4] three patients had ataxia, nystagmus, dysarthria, cataracts, pes equinovarus, and retarded somatic and psychic development characteristic of hereditary cerebello-lental degeneration. However, he did not consider his cases to be examples of a unique entity but rather a variant of Friedreich's ataxia.

Müller[5] described a mentally retarded male reared in an orphanage. Nothing was known about the family. Cataracts were observed at nine months. Strabismus, horizonal nystagmus, ataxia of limbs and trunk, hypotonia, absent tendon reflexes, and a normal toe response to plantar stimulation were also found. A second male apparently unrelated to the first was also described. He too had retardation of mental and physical development and was still unable to stand alone at six years of age. The following signs were noted: bilateral cataracts, ataxia, poorly enunciated speech, nystagmus, hyporeflexia, hypotonia, Babinski on the left, hypogenitalism, genu valgum,* and pes valgus.

Norwood[6] described two cases. The first was a white male who was small at birth, who had retarded mental and physical development, and whose head circumference at two years of age was 17½ inches. Cataracts, strabismus, nystagmus, ataxia, poorly developed muscles with normal tone, normal reflexes, and kyphosis were noted. The hair was depigmented and of the lanugo type.

A female, unrelated to the first patient, showed the same ocular, neurological and skeletal features described in the first patient. Her hair was also depigmented and showed no definite medulla. The hair anomaly had not previously been noted in the Marinesco-Sjögren syndrome. Chromosomal studies in the two patients were normal.

Máttyus et al.[7] described two additional cases. A male adolescent had dysarthria, limb ataxia, coerulear cataracts, hyperreflexia but no Babinski response, spasticity and mental retardation (IQ 61); the circumference of the skull and muscle development were normal. No skeletal deformities were mentioned. He was less than five feet tall.

Their second case was the younger brother of the first patient. He too was retarded mentally (IQ 65). His height was 141 cm. and there was a pes planus. The skull was normal. Cryptorchidism was found and corrected with hormonal therapy. He was ataxic and dysarthric but there was no nystagmus. Cataracts were present. He showed twisting movements of the head. Tendon reflexes were exaggerated and a tendency to a Babinski response was found on one side.

Cases Differing from True Syndrome

The cases described by Géraud et al.[8] under the label of the Marinesco-Sjögren syndrome are, in our opinion, erroneously classified. Bilateral cataracts, cerebellar ataxia, and pes cavus were present; but there were many dissimilarities when compared with other examples of the Marinesco-Sjögren syndrome. The features reported which are not seen in the Marinesco-Sjögren syndrome include an onset of neurological disability and mental deficiency in middle life and sensory deficits. Moreover, the mother of the patients was similarly affected, suggesting dominant rather than recessive inheritance.

A brother and sister thought to have the Marinesco-Sjögren syndrome were described by Zlatoverov and colleagues.[9] However, unlike cases with this syndrome, the boy showed normal development until one year of age, but thereafter there was progressive impairment of both physical and mental growth. Ataxia of gait developed, and by age seven, he had difficulty standing. The corneas were clouded (cataracts?). He died after an unsuccessful

*See Test Your Word Score Page 937.

attempt to perform pneumoencephalography. The post-mortem examination showed evidence of toxoplasmosis, hypoplasia of internal organs, adherence of pericardium to epicardium, increased connective tissue, thickened and opacified meninges, and cystic degeneration of the cerebral cortex. The brain was more firm than normal when sectioned, and the ventricles were dilated. Histological examination showed pyknotic cells with indistinct Nissl substance. Glial proliferation was present. Areas of old necrosis were seen in the region of the dentate nucleus, the third ventricle, and the infundibulum. Perivascular calcifications were present. The sister had a similar rapid course but was not as well described clinically. The rapidly progressive course and normal development in infancy is unlike what has been described in other cases of Marinesco-Sjögren syndrome. This diagnostic label is probably not appropriate for Zlatoverov's cases.

Crome and his colleagues[10] described siblings with congenital cataracts and neurological abnormalities due to unknown cause and included the Marinesco-Sjögren syndrome in the differential diagnosis. However, cerebellar ataxia was not a prominent feature. Renal abnormalities and seizures which were present are not characteristic of the Marinesco-Sjögren syndrome. In our opinion, the clinical picture in Crome's cases is therefore distinct from that shown by the patients with genuine Marinesco-Sjögren syndrome.

Nick et al.[11] described a male with cataracts, cerebellar ataxia, and mental aberrations. He also had extrapyramidal features and seizures. They considered him to be an example of the Marinesco-Sjögren syndrome. However, the cataracts developed in adolescence, the ataxia became manifest at age 35, and the intellectual deficit was not apparent until middle life. In addition, there was a family history of cataracts. Therefore, although there were several features in common with the Marinesco-Sjögren syndrome, the dissimilarities are sufficiently striking to warrant exclusion of this case.

Francois[12] reviewed a number of disorders in which congenital cataracts were seen. None of the disorders, however, included ataxia as a prominent feature and it should not be difficult to distinguish them clinically from the true Marinesco-Sjögren syndrome. In his discussion, Francois accepts the possibility that the spino-cerebellar ataxia of Marinesco-Sjögren syndrome may be replaced by muscular atrophy and cites the report of Dufour et al.[13] as supporting evidence. We hold that cerebellar ataxia is one of the most important features of the Marinesco-Sjögren syndrome; we do concede, however, that muscle wasting and poor muscle development is another feature shown by some affected individuals.

Mild Muscle Disorder

The poor muscle development in our case was noteworthy. The clinical examination, electromyogram, muscle biopsy and slightly elevated creatine phosphokinase were all compatible with the existence of a mild, probably chronic, myopathy. Muscle abnormalities have been mentioned in other cases with this syndrome[2,3] and may be a common feature. The muscle disorder, however, is mild and contributes less to the patient's disability, at least initially, than the cerebellar dysfunction. That the muscle disorder may also be slowly progressive is suggested by Sjögren's long-term followup evaluation of some of his cases. In the family reported by Alter et al.,[3] the degree of muscle wasting was greatest in the oldest affected individual and least in the youngest.

Prominent Features

On reviewing cases reported with hereditary cerebello-lental degeneration, three clinical features emerge as major signs, while others are more variable and may be considered as minor signs. The first major feature includes *cerebellar ataxia.* The ataxia is always present in infancy and results in a marked delay in development of motor skill, such as sitting and walking. The affected individual eventually compensates for this deficit and is able to ambulate. However, walking may be delayed until puberty and is never performed with facility. There is a suggestion that walking ability may again be lost, possibly as a result of progressive muscle weakness rather than ataxia. Dysarthric speech having a child-like quality and nystagmus are also characteristic. Other types of extra-ocular movement disorders are also present but may represent nuclear rather than internuclear defects of innervation. Strabismus is very commonly present.

A second major feature is *cataract*. The type of cataract, however, shows considerable variability.[3] There is some question as to whether the cataract is always congenital, but there is general agreement that it begins very early in life and by three to five years of age is sufficiently severe to reduce visual acuity markedly. Early treatment of the cataract represents the one therapeutic measure available in this disorder which offers much hope of improvement to the patient.

A third major feature is *mental and physical retardation*. The mental retardation is of mild to moderate degree and not progressive. The individual can be trained to carry out simple tasks and manage his personal hygiene quite well. Physical retardation is also of mild degree but is regularly present. The affected individuals have short stature. Our patient was 1.65 meters tall and is one of the taller patients described.

Less Common Features

The clinical features which are common but not invariably present include *skeletal anomalies* of variable nature. Short and misshapen digits on the hands or feet, microcephaly, dental anomalies, kyphosis, rib anomalies, and vertebral body defects, among others, have been described.

Pyramidal tract involvement is present in about half the cases, as evidenced by spasticity and a Babinski response.

Sensory defects are *not* present. The tendon reflexes in some cases are absent, as in Friedreich's ataxia. *Muscle involvement* has not been investigated in any detail, but none of the previously reported cases were robust of build. Studies in our patient suggest that there may actually be a mild myopathic component to the syndrome. The hair anomaly reported by Norwood[6] has not been recognized by other observers.

Genetic Considerations

Inheritance follows a recessive pattern. Consequently, consanguinity of the parents is likely and should specifically be asked about whenever an affected individual is encountered. The fact that cases have now been reported from many widely separated parts of the globe suggests that the gene locus responsible for the syndrome may mutate with a fair frequency. It is doubtful that carriers of the recessive trait disseminated it so widely in different populations, but this possibility cannot be excluded. As expected in single gene disorders, chromosomal studies[6,14] have been negative.

The pathology of the disorder in the nervous system remains to be elucidated. Details available are meager and are based on brain biopsy material or on cases whose classification is open to question.

The biochemical basis of the disorder remains as genetically obscure today as when the syndrome was first described.

Summary

A sporadic case of hereditary cerebellolental degeneration with mental retardation (Marinesco-Sjögren syndrome) has been described, and a myopathic component has been documented for the first time with electrodiagnostic techniques and muscle biopsy. The literature on this rare syndrome has been critically reviewed. Major signs include cerebellar ataxia, cataracts, and mental and physical retardation. Minor signs include strabismus, dysarthria and nystagmus, probably related to the cerebellar involvement; skeletal anomalies including kyphosis, microcephaly, deformities of ribs, hands, and feet; pyramidal signs; and mild myopathy. The syndrome is inherited as an autosomal recessive disorder. The pathology of the brain and the underlying biochemical defect are still unknown.

Placental Localization

The Use of Technetium^{99m} Albumin and the Scintillation Camera*

MERLE K. LOKEN, M.D., Ph.D.†
CHARLES DUNHAM, M.D.†
WILLIAM H. SPELLACY, M.D.†
Minneapolis, Minnesota

THE CLINICAL management of the pregnant subject who has had third trimester vaginal bleeding is simplified if the location of the placenta can be ascertained. Prior to the general availability of short-lived radioisotopes such as technetium^{99m}, attempts were made to localize the placenta using radioactive pharmaceuticals such as I^{131} serum albumin or chromium^{51}-labelled red cells.[1] Considerable effort was then spent on locating the placenta by counting several areas of the abdomen individually. Because of the rather long physical and biological half-life of these preparations, the amount of radioisotope administered was necessarily small, so that the radiation exposure to the patient and the fetus might be maintained within acceptable limits. This small amount of radioactivity precluded the use of conventional scintiphotographic procedures which provide pictorial presentations of the placenta and hence better overall accuracy in placental localization than is possible with spot counting.

In an earlier communication reference was made to the use of technetium-labelled albumin and a scintillation‡ camera for several diagnostic procedures.[2] Among these procedures was localization of the placenta in a manner initially described by McAfee and associates.[3] Since that time several reports of placental localization with technetium-labelled albumin have appeared in the literature.[4,5,6,7]

The purpose of this report is three-fold, first, to review our experience using technetium^{99m}-labelled, albumin in 51 pregnant subjects, secondly, to report on the scintillation (Anger) camera for the localization of the placenta, and finally to study the fetal transfer of radioactivity and thereby assess the radiation hazard of the procedure.

*Supported in part by funds from the Graduate School, University of Minnesota.

With technical assistance of Stephen Bostrom, R.T.

‡See Test Your Word Score Page 937.

Principles and Methods

Technetium^{99m} has a physical half-life of six hours and is obtained from a Mo^{99}-Tc^{99m} generator* by saline elution. Technetium^{99m} decays without beta emission to its ground state, giving off a 140 Kev gamma photon. This photon is nearly ideal for use with the scintillation camera, particularly with a low-energy multichannel collimator now available for use with this instrument.

Technetium^{99m}-labelled albumin is prepared daily in our laboratories. The method is modified after the technique of Stern and associates[8] and requires approximately one hour to complete. Consistent yields of greater than 80 per cent technetium-labelled albumin have been obtained. The small amount of technetium which remains unlabelled is removed by passage of the albumin mixture through a resin column (Dowex-50*). The material is then sterilized by passage through a millipore filter. Aliquots are taken daily for sterility evaluation. Placental scintiphotograms are obtained immediateley after the intravenous administration of 0.5 to 2 millicuries of the labelled albumin. One to two minutes of time was required for each scintiphotogram to be obtained with the scintillation camera.

Results

All of the subjects studied had a digital localization of the placenta performed at the time of delivery. After completion of the delivery a comparison of the two results was made. Excellent correlation was obtained in all but one patient where insufficient numbers of scintiphotograms were obtained in various projections in order to determine whether or not the placenta was located on the anterior or posterior wall of the uterus.

Position of Placenta

Two patients in our series were found to have a central placenta previa and another subject had a marginal placenta previa. In each instance the correct diagnosis was made from the scintiphotograms. Scintiphotograms from the remaining group of patients showed the placenta to be located away from the internal os of the cervix; in all cases this was verified by subsequent digital examination.

Figure 1 shows a scintiphotogram obtained

*E. R. Squibb and Company.

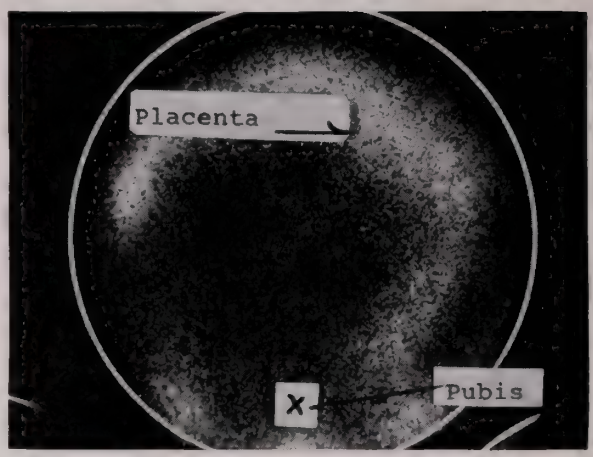

Fig. 1—Scintiphotogram of the anterior projection of the abdomen showing a complete placenta previa.

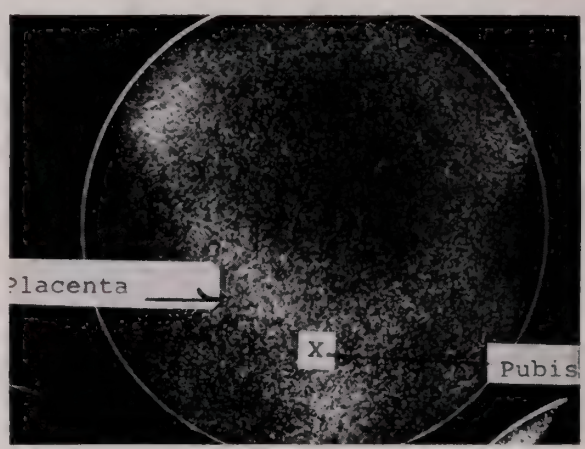

Fig. 2—Scintiphotogram of a marginal placenta previa.

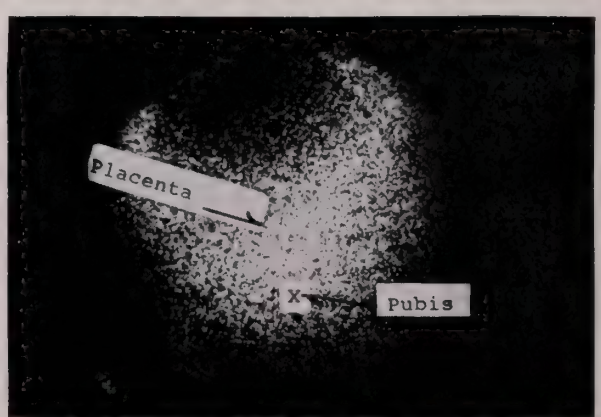

Fig. 3—Scintiphotogram of the anterior abdominal wall showing the placenta in a normal location near the dome of the uterus. Note the radioactivity in blood vessels in the iliac regions and in the uterine wall.

following the administration of one millicurie of technetium^{99m} albumin intravenously. The scintillation camera was directed toward the anterior aspect of the abdomen. The placenta is located near the dome of the uterus to the left of midline. Figures 2 and 3 show scintophotograms from two other patients obtained in a manner similar to that used for the study shown in Figure 1. Figure 2 shows a marginal placenta previa. Figure 3 shows a complete placenta previa.

Radioactivity of the Blood

In ten subjects venous blood was serially obtained for two hours following technetium^{99m} albumin administration and also at the time of delivery. Whenever possible, umbilical cord blood and amniotic fluid were also obtained. These data are summarized in the Table. External counts were made on two of the infants following delivery within three hours of the time of maternal administration of the radioisotope. *In no case was there significant radioactivity found in the infants.*

Discussion

The management of a pregnant subject who is bleeding per vagina is a complex and hazardous problem for the obstetrician. These results together with those published by other investigators indicate that placental localization by the scintiphotographic technique following the administration of technetium^{99m} albumin is a useful diagnostic tool in evaluating this problem. In all of our patients, the placenta was visualized adequately, and in all but one case it was located correctly in the uterus. Three of our patients were found by the scintiphotograms to have placenta previa and all were delivered by cesarean section.

Placental Barrier

Our data indicate that essentially no radioactivity crosses the placental barrier since we did not find any significant radioactivity in the infants following delivery. In one infant, cord blood was found to show some radioactivity (17 per cent of maternal blood counts per cc) which indicates that in this particular study not all of the administered technetium was labelled to the albumin. Thus the removal of any "free" technetium from the labelled albumin preparation prior to its use for placental localization is desirable. However, some clinics are advocating the use of the pertechnetate ion (no albumin label) because of the relatively small radiation dose involved.[9]

Minimal Radiation Dose

The radiation dose to the mother and the fetus appears to be well within acceptable limits. The radiation is considerably below that which would be received by conventional radiographic techniques for evaluation of the placental location. The maternal radiation exposure following administration of one millicurie of technetium-labelled albumin has been estimated by Smith to be 50 millirads to the blood and 3-6 millirads to the total body.[10] Because of the very low transport of this radioisotopic preparation across the placental wall, the fetal dose will be approximately the same as the total body maternal dose (3-6 millirads).

False Results

No false positive or negative results of pla-

centa previa were found in our series. Nonetheless, both results are possibilities and should be watched; for, if there is heavy vaginal bleeding, the pooled vaginal blood which contains radioactivity may give falsely positive scans. A false-positive might also result from excessive technetium in the bladder. This can, of course, be eliminated as a source of error by frequent voiding during the sequential scintiphotograms. A false-negative scan could be obtained in the rare presence of a succinate lobe of the placenta.

Value of Knowing

The final decision as to the obstetrical management in placenta previa depends upon the amount of placenta which overlies the inverval os of the cervix. At the present time this can be determined only by a digital examination prior to delivery. If possible all suspected cases of placenta previa are managed conservatively prior to 36 weeks of gestation in order to avoid the delivery of a premature infant. This can be expensive and inconvenient for both the physician and the patient. One very useful purpose of the placental scan is therefore the safe elimination of most vaginal bleeding cases from this high-risk suspect group, because the placenta will usually be shown to lie away from the lower uterine segment. This information will also encourage the physician to think of the other causes for bleeding in those cases. It will also make the conservative management more intense and cautious in those cases where the placenta is low in the uterus. These latter cases will ultimately come to the operating room for a double-set-up vaginal examination which will then reveal the exact location of the placenta and thus the mode of delivery for that patient.

Summary

The use of technetium^{99m} and the scintillation camera afford a reliable and atraumatic way for determining placental location in the pregnant subject. The radiation exposure to both mother and fetus is exceedingly low (3-6 millirads). The scintillation camera permits several scintiphotograms of the maternal abdomen to be obtained in a short time, usually in less than a half hour.

Blockheads of Different Degrees

I hold that there is every variety of natural capacity, from the idiot to Newton and Shakespeare; the mass of mankind, midway between these extremes, being blockheads of different degrees: education leaving them pretty nearly as it found them, with this single difference, that it gives a fixed direction to their stupidity, a sort of incurable wry-neck to the thing they call understanding. So one nose points always east, another always west, and each is ready to swear that it points due north.—Thomas Peacock

Happiness may be thought, sought or caught, but not bought.—Mutual Moments

Sulfobromophthalein Sodium

Fatal Reactions

REX B. SHAFER, M.D.*
DANIEL H. GREGORY, M.D.*
Minneapolis, Minnesota

SULFOBROMOPHTHALEIN has been widely accepted in evaluation of hepatic function since its clinical application was initially recognized in 1925.[1] Only after 23 years of extensive use was the first non-fatal adverse reaction to sulfobromophthalein dye described, and no fatalities were reported until 1956.[2,3]

Iber listed 14 fatal and 18 non-fatal reactions.[4] He noted that all reactions to sulfobromophthalein are not recognized as such, and of those recognized, not all are reported. Thus the number of reported fatalities represents only a minimal estimation of the incidence. Wang and Jacobson reviewed the literature in 1966 and noted that there were 19 cases with complications, eight of which had been fatal.[5] They reported an additional three cases of adverse reactions without fatality. Their review showed that half of those patients with fatal reactions and one third of those with non-fatal reactions had had previous exposure to sulfobromophthalein. A positive history of allergic sensitivity was noted in 40% of the fatal cases.

The subject of this review is to remind the physician of the potential danger of this diagnostic drug and to include two additional cases of fatality associated with the administration of sulfobromophthalein.

Case Reports

Case 1

A 55-year-old white male farmer entered the Minneapolis Veterans Hospital with a cough productive of yellow sputum, shortness of breath and increasing fatigability. During the previous 11 years, he had experienced progressive shortness of breath and intermittent wheezing attacks that were relieved by bronchodilators. Two years prior to admission he was hospitalized with fever, malaise and chills. Chest x-rays had demonstrated bilateral apical infiltrates. A diagnosis of eosinophilic granuloma was established by lung biopsy. After a three-week course of prednisone (initial dose 60 mgm; then gradually tapered), there was some roentgenographic clearing of the apical infiltrates associated with subjective clinical improvement. Subsequently, however, his

*Department of Medicine, University of Minnesota and Minneapolis Veterans Hospital, Minneapolis.
Send reprint requests to D. H. Gregory, M.D., Veterans Administration Hospital, 54th Street and 48th Avenue South, Minneapolis, Minnesota 55417.

clinical course deteriorated and finally resulted in the present admission.

Abnormal findings on admission, including hepatomegaly, prolongation of the prothrombin time (15 seconds; control 12.5 seconds) and an alkaline phosphatase of 19.8 KAU/100 ml, indicated the need for a sulfobromophthalein test. After injection of 2-3 ml of sulfobromophthalein dye, it was apparent that extravasation had occurred and the procedure was terminated. The attending physician left the room for approximately two minutes. Upon his return the patient was cyanotic, apneic and without a discernible heart beat. Resuscitation efforts were initiated witthin five minutes of the sulfobromophthalein administration and included endotracheal intubation, intravenous and intracardiac epinephrine (1.0 ml of 1:1000) and external cardiac massage. These efforts were unsuccessful.

The postmortem findings showed emphysema, pulmonary fibrosis and histiocytosis. Neither acute bronchial constriction nor laryngeal edema was present. The cause of death was considered to be an anaphylactoid reaction associated with the administration of sulfobromophthalein dye.

Case 2

A 37-year-old white male was admitted to the Minneapolis Veterans Hospital following an episode of infectious hepatitis. After clinical recovery he underwent a sulfobromophthalein retention test without untoward side effects. Three days prior to hospitalization, a repeat sulfobromophthalein test had been performed by his private physician. Immediately following the injection of dye, the patient had developed a severe anaphylactoid reaction and within one hour underwent cardiac arrest. He was successfully resuscitated and immediately hospitalized locally, where anisocoria*, hypotension and bilateral Babinski reflexes were noted.

On the day of admission to the hospital, his temperature rose to 105°, followed by another cardiac arrest. After resuscitation, he required vasopressors, corticosteroids, antibiotics and a tracheostomy. His blood pressure became unresponsive to medical therapy, and he expired the day after admission.

Discussion

Although a cause and effect relationship between sulfobromophthalein and the fatal outcome in these cases cannot be definitely established, it is clear that both patients suffered acute anaphylactoid reactions after the administration of sulfobromophthalein dye. Various adverse reactions have been noted after its use: chills, headache, fever, urticaria, generalized dermatitis, injection discomfort, venous induration at the injection site and serious anaphylactoid reactions.

Mateer et al., in a review of liver function tests, reported that such minor symptoms as chills, headaches and faintness were occasionally seen after the administration of sulfobromophthalein.[6] Stempien and Rosenquist reported that thrombophlebitis occurred in the injected vein in 0.6% of patients receiving sulfobromophthalein injections.[7]

Incidence

To date, 14 fatal and 18 non-fatal reactions to sulfobromophthalein have been recorded in the literature. An allergic history was recorded in 14 of these cases. Three patients had positive allergic histories and two others had asthma. In one case there was a family history of asthma. In the remaining cases, there was neither a personal nor a family history of allergy.

In at least eight of the cases previously reported, including three fatal reactions, there was no clear history of receiving sulfobromophthalein prior to the injection that caused anaphylaxis. Nine cases were known to have had previous tests without adverse effects, even though in two of these there had been extravasation of dye on previous tests.

The use of sulfobromophthalein dye is contraindicated in patients with an allergic or asthmatic history. Case 1 had an 11-year history of intermittent wheezing and a documented, antecedent allergic reaction. The administration of sulfobromophthalein dye to this patient was complicated by extravasation and resulted in a fatal outcome.

In Case 2 there was an apparent anaphylactoid reaction following the injection of sulfobromophthalein dye in a patient who had previously received the dye without adverse effect. Apparently, significant central nervous system damage had occurred before vigorous attempts at therapy were possible.

Contraindication

From the previously reported adverse reactions to sulfobromophthalein,[4,5,8] certain factors appear responsible and should be considered prior to the administration of the dye. These include: (1) a complete allergic history should be obtained from the patient; (2) patients who have previously experienced adverse reactions to sulfobromophthalein should not receive repeat tests; (3) observable extravasation of the injected dye into the extravascular

*See Test Your Word Score Page 937.

tissue should terminate the injection; and (4) tests for sulfobromophthalein retention should not be carried out without specific indications. In a patient with a previously demonstrated thrombophlebitis or an allergic reaction to the extravasated dye, extreme care should be taken if another test is indicated.[9]

Precautions to be taken during administration of the dye include: (1) administration should be done by a person who is prepared to deal with an acute anaphylactoid reaction; (2) the patient should be observed during the administration of the dye and at least five minutes afterwards; (3) the dye should be administered slowly over a period of five minutes; (4) extravasation of the dye should be avoided, and when observed should terminate the administration; and (5) vigorous resuscitation should be attempted in the event of an anaphylactoid reaction, for in a significant percentage of patients with adverse reactions to sulfobromophthalein, such efforts have been successful.[4,8]

Summary

During the 40 years that sulfobromophthalein sodium dye has been used as a test of hepatic function, there have been very few serious adverse reactions recorded in the literature. To date, 32 anaphylactoid reactions, including 14 with fatal outcome, have been reported. Continued reporting of serious or fatal adverse reactions to sulfobromophthalein should constantly alert the physician to the potential dangers of this frequently used test.

"Make-Do" On the Frontier

A horse kicked a Klamath Falls, Oregon, ranch boy in the head and fractured his skull. Dr. John Patterson, called to the unconscious child's bedside, knew he had to relieve the pressure on his brain by removing a piece of bone, but he did not own a trephine, the cylindrical saw that surgeons use in this delicate operation. The doctor was undismayed. His frontier medical practice had accustomed him to "making do."

He took a thimble from the mother's sewing basket, sawed off the closed end, and filed teeth into the cut edge. Then he nailed the thimble to the end of a duster handle with a shingle nail. Cutting off the head of the nail, he filed it to a point so that he could center the instrument on the section of the boy's head he had to incise. Unlike many western doctors, Dr. Patterson had heard of the importance of sterilization, and he boiled his contraption in bichloride of mercury before setting to work. His patient recovered.*

Second Look Love

I am not one who do not believe in love at first sight, but I believe in taking a second look.—Henry Vincent

Medical Age Control

A certain Moscow polyclinic specializes along very unusual lines. The people who come there on certain days of the week hardly qualify as patients requiring medical aid. They have no complaints: neither of ailments and pains, nor of weakness and prostration. They are perfectly healthy and fit, and work at various institutions in different, sometimes highly important, capacities.

At the polyclinic they are regularly examined, investigated by the latest exacting methods, and advised on their mode of life, on how to work, how and what to eat, and how to rest. If symptoms of a disease, unsuspected by the patients, are discovered at the examinations, they are treated on the spot or sent to a clinic.

All these people have only one thing in common—their age. They are all past fifty, *all on in years, all on the threshold of old age.**

The doctors examine them, and those whose organs and tissues already show changes that are as yet slight and harmless but may turn into dangerous debilities if allowed to develop, are treated with the aim of arresting the process. This refers to persons with disorders such as high blood pressure, sclerosis of the connective tissue, thickening of the blood vessels, or atherosclerosis.

The doctors at the polyclinic are called upon to detect the incipient stages of these and similar debilities as early as possible. The visitors are given precise instructions on how to arrest the development of morbid changes. Persons with early symptoms of a disease are told how they must work and rest, and how to eliminate all harmful influences from their environment at work and at home. Regular examinations permit the doctors to control the loyal execution of all their therapeutic and preventive measures.

This is the first step of a remarkable undertaking aimed at turning the old age of people whose organisms already show signs of time's destructive action, into an unclouded and industrious period of their lives.†

John Hunter—Lecturer

Lecturing was always an unpleasant task to Hunter who never lost his fear of addressing a class. He would brace himself each time by taking thirty drops of laudanum before facing the large audiences who came to hear his ideas on embryology, physiology, "animal chemistry," properties of matter, and the "life of the blood." The lectures took a great deal of his time and energy to prepare, since each was illustrated with materials from his unique museum, and he was continually revising and adding to his notes in the light of new observations. "You had better not write down that observation, for very likely I shall think differently next year," he would say to a prodigious note-taker. To one student who pointed out that he had just contradicted a statement of the year before, he replied: "Very likely I did; I hope I grow wiser every year."*

Mediastinoscopic Diagnosis of Sarcoidosis*

ARVID F. JOHNSEN, M.D.
ARNDT J. DUVALL III, M.D.
SEVERIN H. KOOP JR., M.D.

Minneapolis, Minnesota

Sarcoidosis, a disease of unknown etiology, may involve multiple sites in various organ systems. Many areas are available for purposes of diagnostic biopsy. Obviously, the simplest biopsy procedure yielding histologically positive material is the procedure of choice. In suspected cutaneous and oral sarcoidosis, the preferred biopsy sites are the skin and mucosa, skeletal muscle biopsy when there are muscle symptoms, liver biopsy when the liver is enlarged or there are signs and symptoms of liver dysfunction, and biopsy of palpable nodes, e.g., epitrochlear.

Exceptions

However, a large number of affected patients do not qualify for the above procedures. These patients may have respiratory symptoms which prompt further evaluation, or they may have radiographic pulmonary abnormalities which are discovered fortuitously. For these patients there are several alternatives:

1. The clinical diagnosis of sarcoidosis may be made without histologic proof and the patient can be followed periodically for evolution or resolution of his disease. This course may be defensible when classic bilateral hilar adenopathy is present. However, many patients with suspected sarcoidosis may actually harbor an entirely different or additional disease process. If this is true, delay may be harmful to the patient.
2. The intradermal Kviem test for sarcoidosis can be given. Although reliable when a good antigen is available, this test usually requires about six weeks before a positive diagnosis by biopsy of the test site can be obtained.
3. Endoscopic procedures with biopsy and/or scalene node biopsy may be done.
4. An alternative is mediastinoscopy and biopsy of the hilar or paratracheal lymph nodes.

The purpose of this paper is to report our

*Presented at the Minnesota Academy of Ophthalmology and Otolaryngology Meeting, December 8, 1967.

experience using mediastinoscopy in the diagnosis of sarcoidosis.

Study Group

In the first 100 mediastinoscopies, the basic technique of Carlens[1,2] was followed with the exception of 51 cases which were done under local rather than general anesthesia. Knowledge of the anatomy is mandatory to avoid injury to major vessels and nerves.

Procedure

A transverse suprasternal notch incision approximately 4 cm. in length is made, and dissection carried down through the last layer of pretracheal fascia. Finger dissection is continued inferiorly, after which the mediastinoscope, an instrument resembling a laryngoscope, is introduced. Further dissection is done with a velvet-eye sucker tip.

A search for lymph nodes is made anteriorly, paratracheally, and along the main stem bronchus at and below the carina. The area of contemplated biopsy must be aspirated first with a long needle to avoid vascular injury and hemorrhage.

In active sarcoidosis the nodes are characteristically large and plump with a bluish violet color (Figure 1). In chronic long-standing disease the nodes are small, firm and grey in color. Once the tissue has been obtained the area is inspected for bleeding. If proper precautions are taken this should be negligible.

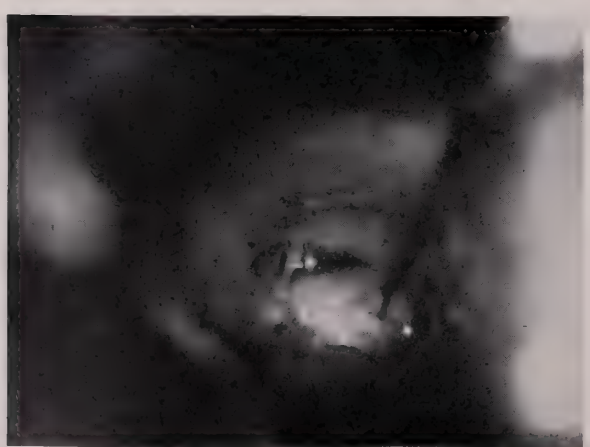

Fig. 1—View through the mediastinoscope. Large subcarinal sarcoid node being needled prior to biopsy. This node was not visualized by mediastinal planigraphy. Note pulmonary artery in upper right.

The incision is then closed snugly in layers.

Results

A diagnosis of sarcoidosis was made histologically in 16 of 100 patients having mediastinoscopy. Table 1 demonstrates that the radiographic picture is by no means stereotyped.

In five patients non-diagnostic bronchoscopy, including bronchial biopsies, preceded mediastinoscopy. In three patients scalene node biopsy was non-diagnostic. To our knowledge, no patient having a negative mediastinoscopy has subsequently been found to have sarcoidosis.

Discussion

The application of mediastinoscopy has grown considerably in recent years as accumulated data continues to support its safety and versatility. In our first 100 procedures, complications in the patients consisted of a left recurrent nerve paralysis in two individuals with extensive intrathoracic neoplasms, and one minimal pneumothorax which resolved without treatment. There have been no deaths. Postoperative antibiotics are no longer used. There has been no instance of mediastinitis, although a temperature spike often follows the procedure.

The results of thousands of mediastinoscopies have been reported in the world literature. The complication rate of our series parallels that of other large medical centers.[3,4] The mortality rate attributable to this procedure should be nil. We also feel the morbidity is less than that associated with scalene node biopsy.[5,6]

Effectiveness

The outstanding merit of mediastinoscopy

Maassen	52	35%	26	62%	59	100%
Bergh et al.					33	100%
Carlens	56	20%			123	96%

*Carlens, E.: Mediastinoscopy. Ann. Otool. 74:1102, 1965.

is its very high diagnostic yield. Comparison studies from other centers substantiate this[7-10] (Table 2). Since the chest lesion is usually of undetermined etiology, mediastinoscopy may also provide histologic evidence of other disease processes, e.g., carcinoma, lymphoma, benign cysts, histoplasmosis, etc. In these instances patients are spared thoracotomy not only for certain benign lesions but also for malignant lesions which have extended beyond the confines of resectability.[11]

Bronchoscopy

Bronchoscopy, although not comparing favorably in terms of percent yield, does afford the opportunity of inspecting the endobronchial tree which may host not only the granuloma of sarcoidosis but other lesions as well. We feel that bronchoscopy should precede mediastinoscopy except in young people with no respiratory symptoms and classic x-ray findings. Both procedures can easily be accomplished at the same sitting.

Summary

In 100 mediastinoscopies sixteen cases of sarcoidosis were diagnosed. Three of these patients had negative scalene node biopsies and five had negative bronchoscopies and bronchial biopsies. None of the patients with negative mediastinoscopies have been found subsequently to have sarcoidosis. In this series there was minimal morbidity and no mortality. We believe that in the absence of palpable supraclavicular nodes, mediastinoscopy deserves priority over scalene node biopsy because of its higher diagnostic yield and safety.

The people who find prosperity just around the corner—usually know which corner to turn.—Roster

Celestial Bed

James Graham: Quack

Graham was a remarkable quack: one of the early electrotherapists. The properties of electricity had only just become known and queues of patients waited at his rooms for the privilege of sitting on his "magnetic throne" or lying in an "electric bath."

The door of his Temple was always open, so that the poor might enter as freely as the rich. All that was demanded of the poor was a fee of six guineas. Once this formality was over, rich and poor males were alike conducted to the Great Apollo Apartment. Here the high priest himself lectured every day. Soft music always preceded his discourse, and at appropriate moments his audience received mild electrical shocks from the carefully wired chairs in which they were seated. As a grand finale an enormous spectre came up through the floor and handed to Graham bottles of his famous "aetherial balsam," guaranteed to promote all sorts of things.

Graham never had as many adherents for his mud-baths and open windows as were attracted by his electrical nonsense and the "aetherial balsam" which guaranteed fertility. If, despite the guarantee, the aetherial balsam did not promote a successful conception and lead to the production of the loveliest possible children, Graham placed at the disposal of his clients his wonder of wonders, the innermost mystery of the Temple of Health. This was his Celestial Bed, which was guaranteed to cure sterility.

The bed was in the centre of a spacious room pervaded always by rich scents and perfumes, and in which could be heard soft music from a string orchestra in an adjoining room. It was supported on six massive glass pillars and bedecked with blue satin. The slightest movement of the occupants made it oscillate rhythmically, and there ran through it electrical currents varying in intensity with the movements of the bed. This magnificent device was at the disposal of any lady and gentleman, preferably married. The price for one night in the bed, with breakfast, was fifty guineas. Graham said, in his Lecture on the Generation, Increase, and Improvement of the Human Species, published in London in 1784:

"Superior ecstasy which the parties enjoy in the Celestial bed is really astonishing and never before thought of in this world; the barren certainly must become fruitful when they are so powerfully agitated in the delights of love."

Graham was a shrewd investor and he reaped enormous dividends. Anyone who had not slept in the Bed was regarded by the world of fashion with the gravest suspicion. This vogue lasted for three most profitable years, at the end of which Graham returned to his native Edinburgh, there to preach the virtues of his mud bath. In his declining years he became first religious and later maniacal. He died suddenly in 1794.*

*Harvey Graham: A Doctor's London, 1952.

Esther B. Clark, M.D.

Doctor Esther B. Clark is a native born Californian who has practiced pediatrics in Palo Alto for 40 years. She has been the Head of the Department of Pediatrics of the Palo Alto Clinic since 1927. A member of the American Physicians Art Association, she has won many awards including a gold medal.

The picture on the cover, "California Foothills", was taken on Kodacolor film of a scene near some property she owns in Mendicino County, 200 miles north of Palo Alto.

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

burning
itching
discharge
of trichomonal vaginitis...

Flagyl®

tablets/inserts

brand of

metronidazole

brings
• clinical cures
• microscopic cures
• culture cures

For the most widespread form of vaginitis the most widely successful therapeutic agent, Flagyl, is clearly indicated.

In trichomonal vaginitis, most physicians have reported a cure-rate of 95 per cent or more with Flagyl when infected male partners are treated concurrently and when treatment is repeated for occasional refractory infections in women.

Among the few patients who do not respond to Flagyl are those who may not have taken the prescribed dosage and those who may have been reinfected.

This high rate of cure obtained with Flagyl is unparalleled. Only systemically active Flagyl reaches the hidden reservoirs of reinfection in male and female genitourinary tracts.

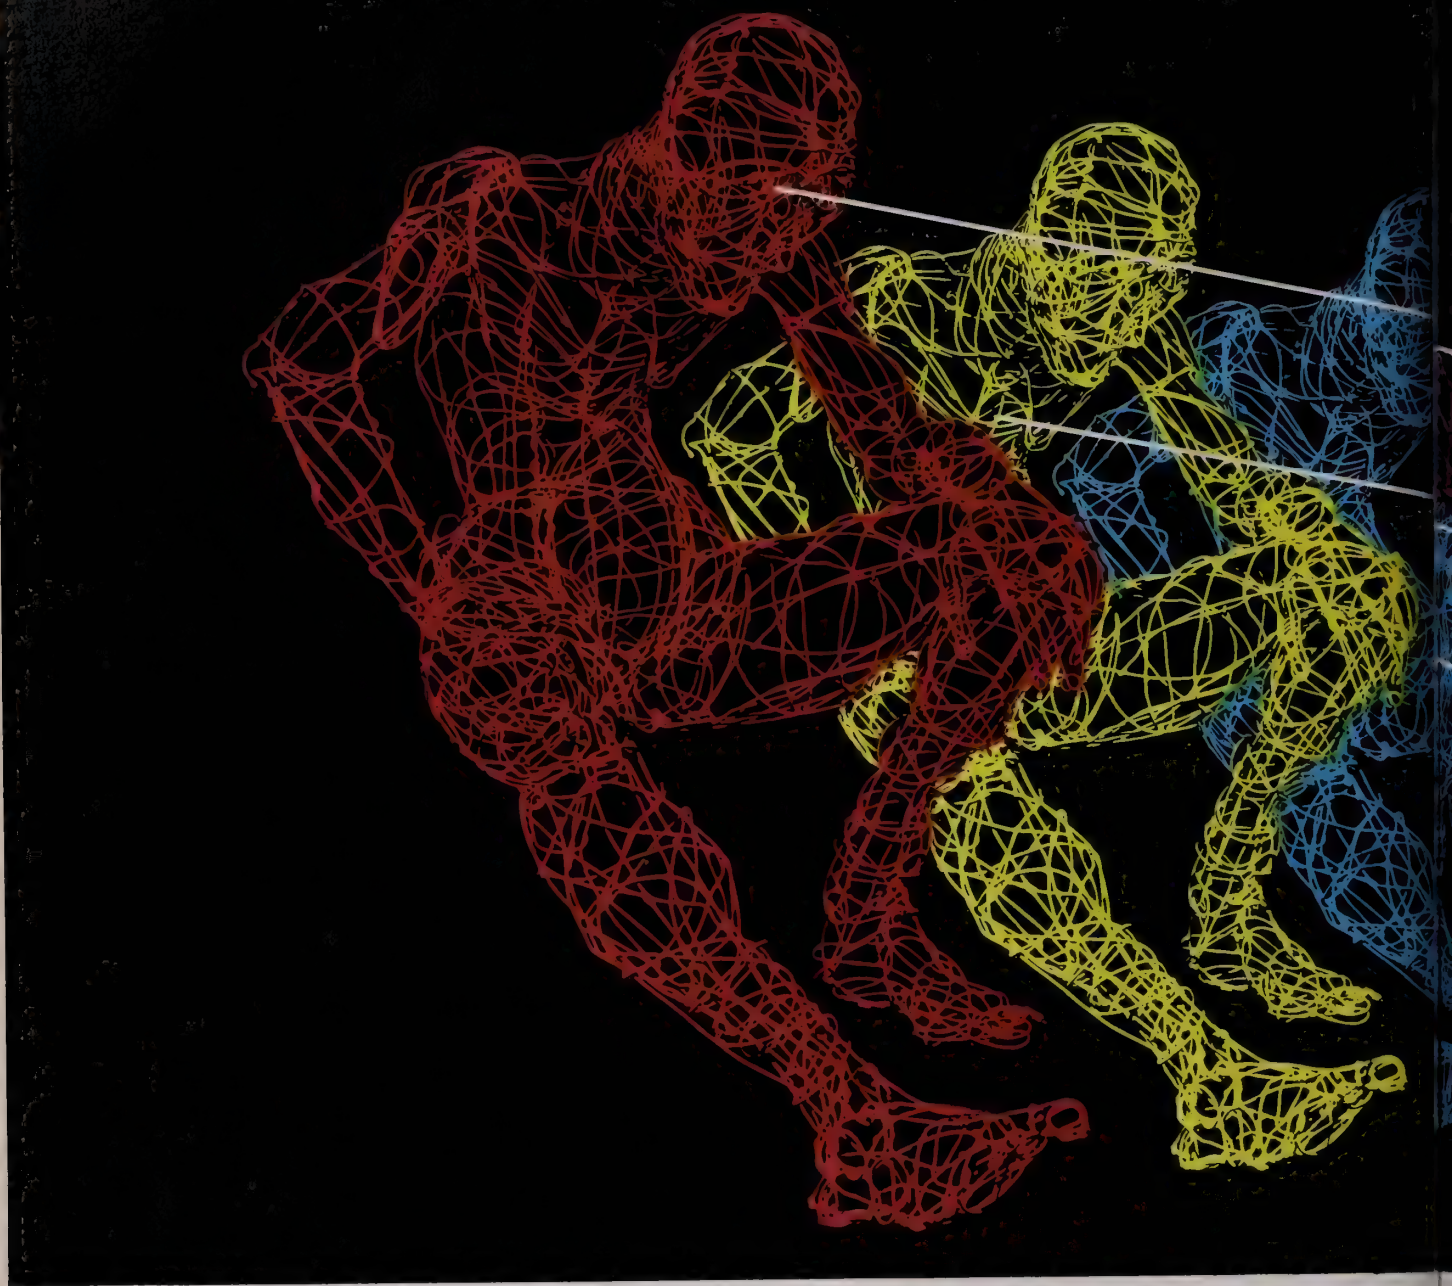
Indications: Flagyl is indicated only in the treatment of trichomoniasis in both the male and female.

Contraindications: Pregnancy; disease of the central nervous system; evidence or history of blood dyscrasia.

Precaution: Complete blood cell counts should be made before, during and after therapy, especially if a second course is necessary.

Side effects: Infrequent and minor side effects include nausea, metallic taste and furry tongue. Gastrointestinal disturbances, flushing and headache sometimes occur, especially with concomitant ingestion of alcohol. The taste of alcoholic beverages may be altered. Other effects, all reported in an incidence of less than 1 per cent, are diarrhea, dizziness, vaginal dryness and burning, dry mouth, rash, urticaria, gastritis, drowsiness, insomnia, pruritus, sore tongue, darkened urine, anorexia, vomiting, epigastric distress, dysuria, depression, vertigo, incoordination, ataxia, abdominal cramping, constipation, stomatitis, numbness or paresthesia of an extremity, joint pains, confusion, irritability, weakness, cystitis, pelvic pressure, dyspareunia, fever, polyuria, incontinence, decreased libido, nasal congestion, proctitis and pyuria. Elimination of trichomonads may aggravate candidiasis.

Dosage and Administration: In women: one 250-mg. oral tablet three times daily for ten days. A vaginal insert of 500 mg. is available for local therapy when desired. When used, one vaginal insert should be placed high in the vaginal vault each day for ten days; concurrently two oral tablets should be taken daily.



In men: When trichomonads are demonstrated, one 250-mg. oral tablet twice daily for ten days in conjunction with treatment of his female partner.

Dosage Forms: Oral tablets—250 mg.
Vaginal inserts—500 mg.

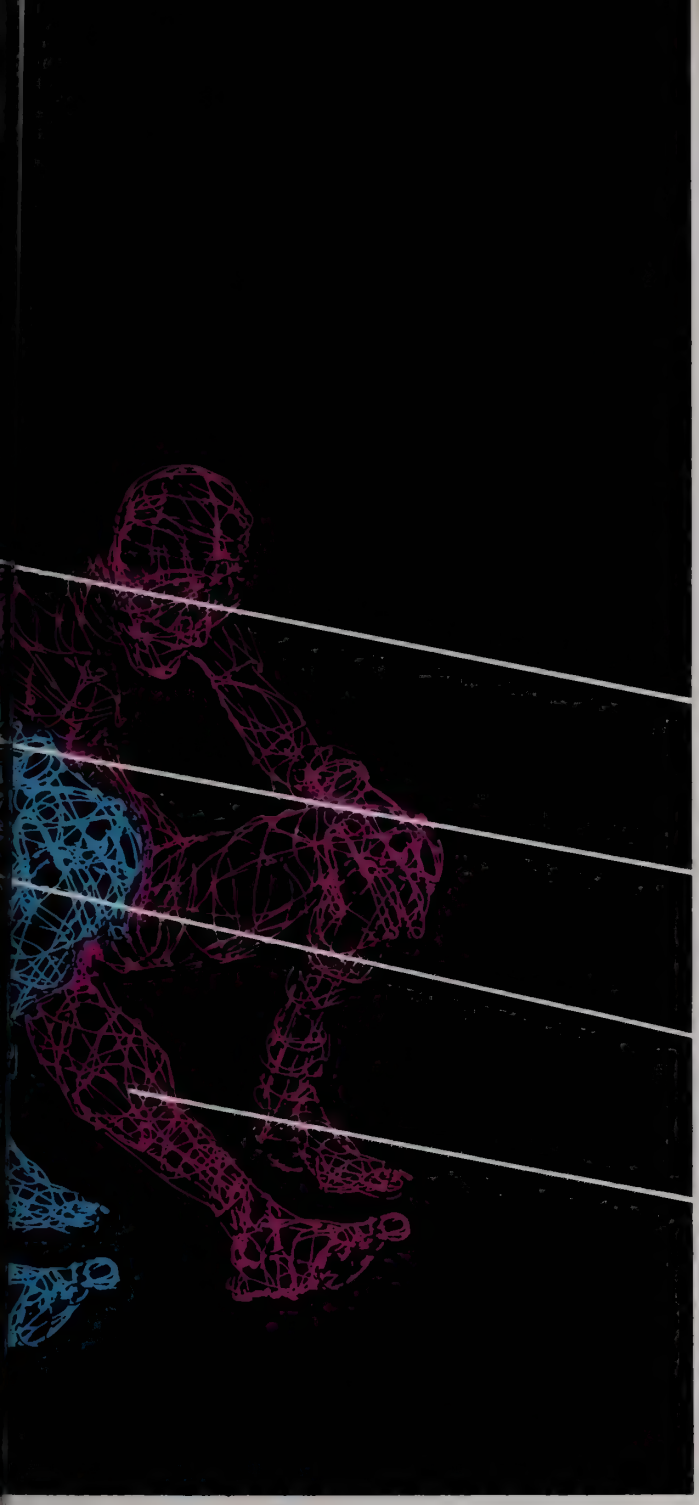
Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	150	mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin (The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)	7.5	mcg.
Iron, Elemental (as Ferrous Fumarate)	110	mg.
Ascorbic Acid (Vitamin C)	75	mg.
Folic Acid	1	mg.



Indications: Trinsicon® (hematinic concentrate with intrinsic factor, Lilly) is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia.

Contraindications: Hemochromatosis and hemosiderosis.

Precautions: Anemia is a manifestation that requires appropriate investigation to determine its cause or causes.

In pernicious anemia, the use of folic acid without adequate vitamin B_{12} therapy may result in hematologic remission but neurological progression. Adequate doses of vitamin B_{12} (parenteral, or oral with potent intrinsic factor as in Trinsicon® [hematinic concentrate with intrinsic factor, Lilly]) usually prevent, halt, or improve the neurological changes.

As with all preparations containing intrinsic factor, resistance may develop in some cases of pernicious anemia to the potentiation of absorption of physiological doses of vitamin B_{12}. If resistance occurs, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary. No single regimen fits all cases, and the status of the patient observed in follow-up is the final criterion for adequacy of therapy. Periodic

You can treat combined deficiencies with

Trinsicon®

—the multifactor hematinic

Vitamin B_{12} plus intrinsic factor (15 mcg. B_{12} activity)—helps provide adequate levels of this important vitamin.

Folic acid (1 mg.)—treats nutritional macrocytic anemias and/or malabsorption syndromes.

Ascorbic acid (75 mg.)—augments the conversion of folic acid to its active form and helps iron absorption.

Iron (110 mg.)—treats hypochromic anemia.

clinical and laboratory studies are considered essential and are recommended.

Adverse Reactions: In rare instances, iron in therapeutic doses produces gastro-intestinal reactions, such as diarrhea or constipation. Reducing the dose and administering it with meals will minimize these effects.

In extremely rare instances, skin rash suggesting allergy has followed oral administration of liver-stomach material. Instances of apparent allergic sensitization have also been reported after oral administration of folic acid.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a standard response in the average uncomplicated case of pernicious anemia.)

How Supplied: Pulvules Trinsicon® (hematinic concentrate with intrinsic factor, Lilly), in bottles of 60 and 500. [032566]

Lilly

Are your patients confused by ad claims? by shapes and sizes? by strange-sounding ingredients? When they need fast relief from pain, you can reassure them that aspirin is still the strongest analgesic they can buy without your prescription. And Bayer is 100% aspirin. No wonder Bayer works wonders.

the antacid puzzle

In peptic ulcer:

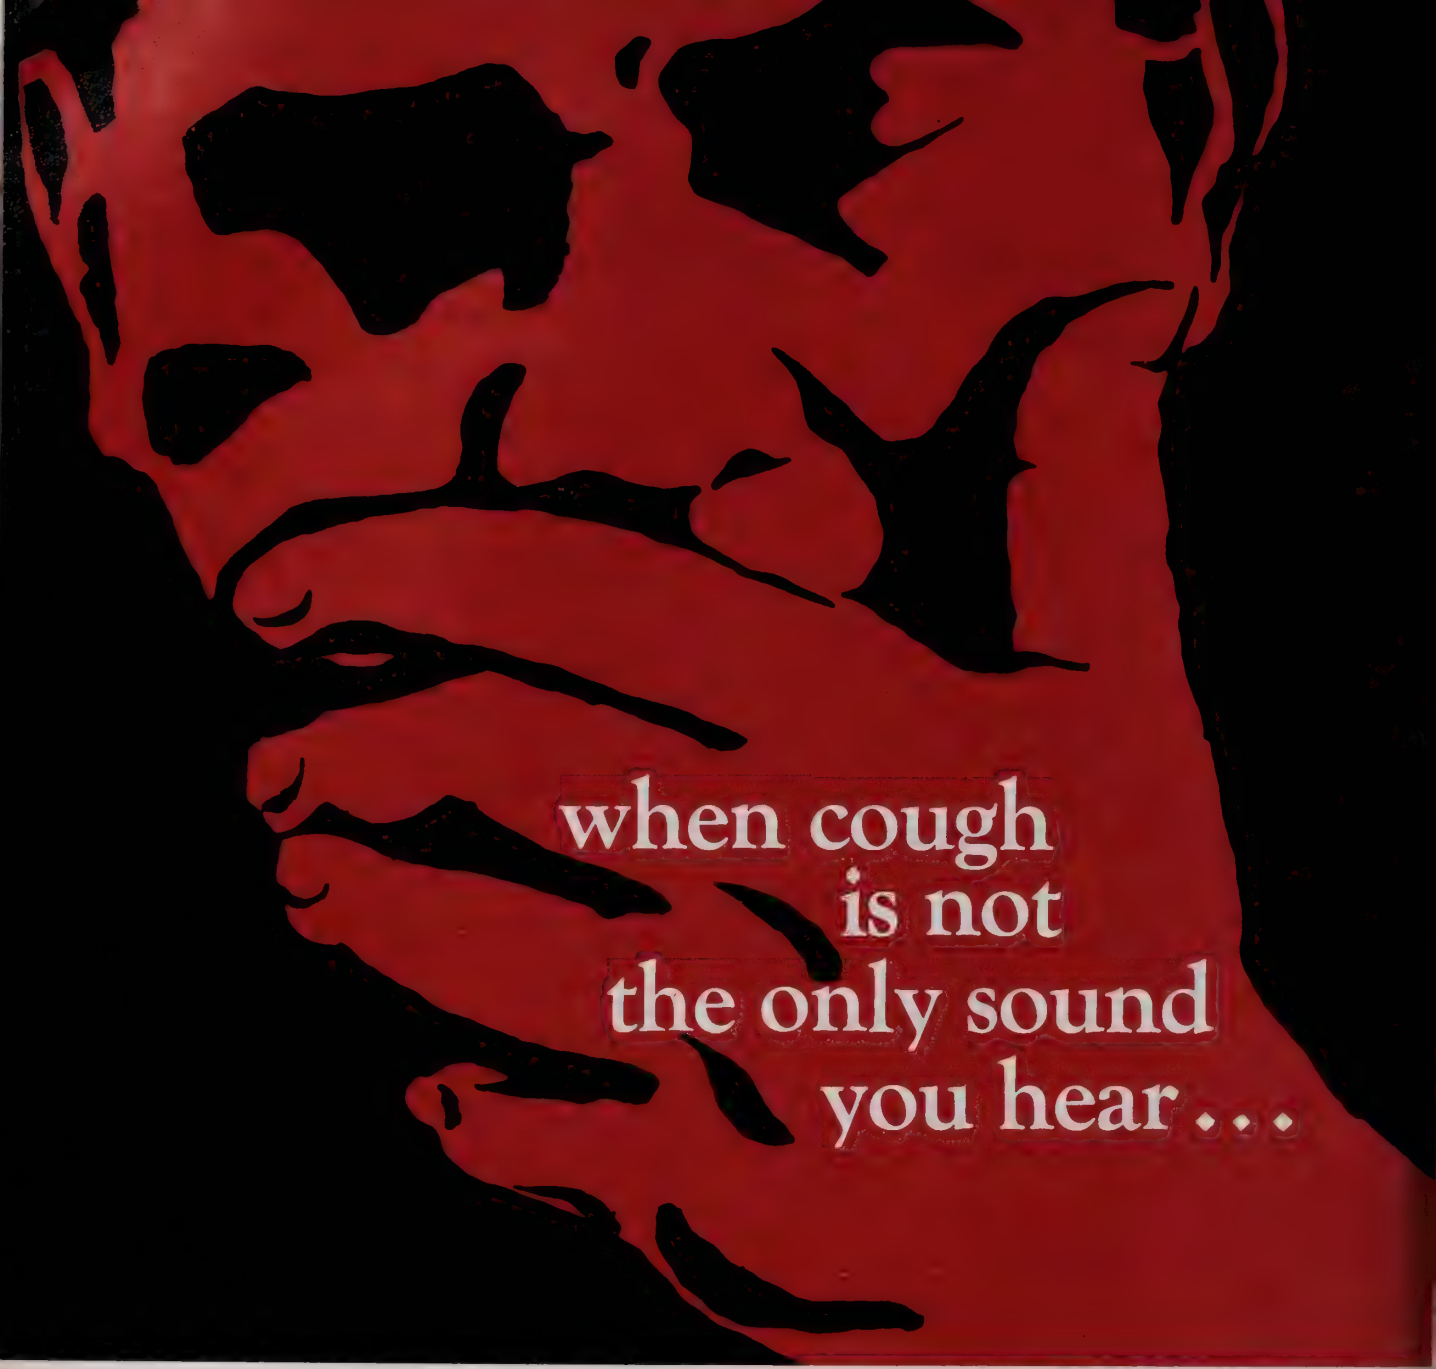
solved by Mylanta®

aluminum and magnesium hydroxides *plus* simethicone

"will it ease the pain?"

Mylanta helps relieve ulcer pain with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

will it help "my gassy stomach"?



Mylanta *also* contains simethicone: for concomitant relief of G.I. gas distress.

"will this one taste O. K.?"

The *prolonged* acceptance of Mylanta was recently confirmed in 87.5% of 104 patients—after a total of 20,459 documented days of therapy.* *Danhof, I. E.: Report on file.

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. *Dosage:* One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

Stuart Division/Pasadena, Calif.
ATLAS CHEMICAL INDUSTRIES, INC.

OMNI-TUSS® b.i.d.

. . . **because** OMNI-TUSS is indicated for cough associated with upper respiratory tract infections, bronchitis, bronchiectasis, bronchial asthma, emphysema, sinusitis and rhinitis, hay fever, or other allergic conditions. Any of these conditions may exhibit the general symptom syndrome—coughing, wheezing, bronchospasm, and tenacious mucus—which may benefit from the antitussive, bronchodilative, antihistaminic, and expectorant action of Omni-Tuss.

The therapeutic usefulness of Omni-Tuss is enhanced by a unique resin complex formulation providing the clinically desirable advantages of: (1) uniform drug availability throughout an extended period, (2) 8 to 12 hours of symptomatic control, (3) minimal dosage requirement, (4) minimal side effects.

Economical, efficient **b.i.d.** dosage—extremely well-tolerated by children, 6-12, and adults.

'Omni Tuss' Suspension: Each teaspoonful (5 cc.) contains 10 mg. codeine (Warning: May be habit-forming), 5 mg. phenyltoloxamine, 3 mg. chlorpheniramine, 25 mg. ephedrine, all as cation exchange resin complexes of sulfonated polystyrene, and 20 mg. guaiacol carbonate.

Available on prescription only. Class X exempt narcotic. Permissible on oral prescription.

Dosage: *Adults:* 1 teaspoonful (5 cc.) q12h.
Children (6-12 *years*): ½ teaspoonful q12h.

Side Effects: Minimal, but when encountered may include jitteriness, nausea, drying of mouth, insomnia, constipation, which disappear upon adjustment of the dose or discontinuance of treatment.

Precautions and Contraindications: For complete detailed information, refer to package insert or official brochure.

Editorials

The Vineberg

*"Chirurgic is too important a branch of medicine to leave to the Chirurgeons."**

MANY SOURCES of extra-coronary blood supply have been brought to the heart of dog and man by ingenious surgeons during the past 25 years. Interest today, however, centers about the left ventricular implantation of internal mammary arteries, the Vineberg procedure.[1] Variations of this procedure with one internal artery implanted, with two vessels used, one anteriorly and one posteriorly, and with other modifications have been done in over 500 cases at the Cleveland Clinic. They indicate that 90 per cent of the implanted arteries stay open.[2] Operative mortality is reported from 4 to 7 per cent.[3] The late mortality is in the neighborhood of 10 per cent.[4]

In patients with severe angina pectoris the clinical results are stated to be excellent. But there is a large placebo effect to be discounted, especially noted in the good results of simple internal mammary artery ligation, or even of a sham thoracic incision.[5]

Sones et al. demonstrated angiographically that the coronary circulation could be filled from the implanted mammary vessels.[6] A recent study by Gorlin and Taylor suggests that the operation is followed by a slight change from anaerobic to aerobic myocardial metabolism.[7]

The Vineberg procedure and variations thereof will be tried in many centers in the immediate future. These operations, however, must still be considered to be in an experimental stage. Anatomical demonstration of cross-connections and patency are of interest, but what is needed is evidence of blood flow through the new channels. Comparative data on operated and nonoperated groups of patients also must be accumulated, showing changes in recurrence of myocardial infarction and mortality.

Centers electing to proceed with this therapy should consider Sabiston's[8] indications: 1. An established diagnosis of coronary arterial occlusion by arteriography, 2. Uncontrolled angina pectoris, and 3. Evidence that there has not been an acute myocardial infarction in the previous four to six months.

Any group of anginal patients subjected to surgery for relief of pain will be, selectively, those patients who react poorly to pain, and those patients who seek maximal therapy, i.e., surgery for pain. These include the neurotic patients who, though they may be demonstrated to have coronary disease, may actually suffer from the neurosis rather than the arteriosclerosis. Patients chosen for surgery

*Post Talmudic aphorism attributed to Rabbi ben Jácob.

Some U.R.I. patients are more miserable than others.

That's why we make Novahistine® tablets in two different formulations.

And let you control the dosage.

Each Novahistine LP tablet contains phenylephrine hydrochloride, 25 mg.; and chlorpheniramine maleate, 4 mg. Each Novahistine Singlet tablet contains phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; and acetaminophen, 500 mg.

With Novahistine LP tablets and Novahistine Singlet™ tablets, you have the range and flexibility of decongestant dosage that lets you prescribe for the needs of the individual patient. Novahistine LP tablets are most useful for relief of nasal congestion in patients without pain or fever.
Novahistine Singlet tablets, which provide analgesic-antipyretic effect, as well as decongestant action, are indicated for upper respiratory infections accompanied by pain, aches and fever.

Whether you prescribe Novahistine LP or Novahistine Singlet, a total daily dose of 3 or 4 tablets will usually provide effective, continuous relief.
Use cautiously in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention.
Caution ambulatory patients that drowsiness may result.

DOW **PITMAN-MOORE** Division of The Dow Chemical Company, Indianapolis

"Nothing else I've tried seems to work, so I decided to give you a crack at it."

should first be evaluated by a cardiologist. Demonstration of coronary disease, even severe coronary disease, is at present an inadequate indication for surgery in the absence of related symptoms, especially incapacitating angina pectoris.

Myocardial infarction has its highest mortality in the first six months, during which the danger of surgery is greatest. After this period the low mortality from the disease must be considered along with the mortality from surgery. Thus myocardial infarction alone affords unsure grounds for surgical intervention. Whether or not patients in heart failure may be benefited by this type of surgery is at present unknown. Internal mammary implantation should prove its value in severe angina before it is extended to other groups of patients in whom the yardstick of pain relief is not available. Pain is a subjective measure fraught with uncertainty.[9] The psychological effect upon the patient whose symptoms will be keenly resolved under *General Anesthesia* by *Vascular Surgery* in an *Open Chest* procedure can be literally overwhelming.

Evaluation of long-term results, of subjects followed five years or more, should decide the issue.

Angiographic demonstration of disease is still too new a method to be considered as an over-riding indication for surgery. Fifteen per cent of young American males dying of trauma in the Korean war had coronary narrowing up to 50 per cent or greater.[10] This group is in need of treatment, but not surgical treatment.

Finally, the evaluation of results must also be made by the medical cardiologist, comparing the operative series of cases with similar groups conventionally treated.

Efficiency Expert

An efficiency expert is a man who knows less about your business than you do and gets paid more for telling you how to run it than you could possibly make out of it even if you ran it right instead of the way he told you to.*

*Jacob Braude: Speaker's Encyclopedia.

Men's virtues have their seasons even as fruits have.—Unknown

A proposal to help you manage congestive heart failure patients:

Initiate therapy with **Hydromox*** Quinethazone 100 mg. (two 50 mg. tablets) daily for 15 days

Many patients in congestive heart failure may obtain the greatest benefit from HYDROMOX Quinethazone when it is given in a single daily a.m. dose of 100 mg. (two 50 mg. tablets). Diuresis is usually rapid and effective in reducing symptoms within the first critical days. We suggest continuing clinical evaluation over a 15-day period of therapy. If results are satisfactory, a reduction to 50 mg. (1 tablet) daily will usually be adequate for maintenance.

Precautions: Electrolyte abnormalities may be aggravated or produced. Caution is important during prolonged or intensive therapy and when salt intake is restricted. Hypokalemia has been mild and infrequent, and other electrolyte abnormalities rare. The possibility of potassium depletion and its toxic sequelae must be kept in mind, particularly in cirrhotics and patients receiving digitalis. As a preventive measure the use of foods rich in potassium, such as orange juice, may be desirable. Although not a thiazide, HYDROMOX may possess certain characteristics of the thiazides. They have been known to cause jaundice with liver involvement and pancreatitis; hematological complications such as purpura with or without thrombocytopenia and leukopenia (neutropenia); increases of serum uric acid; decreased glucose tolerance as evidenced by hyperglycemia and glycosuria thus aggravating or provoking diabetes mellitus and azotemia in patients with renal disease; photoallergy. Discontinue use a few days prior to elective surgery. When added to a regimen that includes ganglionic-blocking agents, the dosage of these latter preparations should be reduced. Also reduce dosage when one or more of these antihypertensive agents is added to an established HYDROMOX regimen. Contraindicated in anuria. Observe for possible hematologic complications.
Side Effects: Skin rash; gastrointestinal disturbances (chiefly nausea), weakness, dizziness. These seldom require cessation of therapy, and can be relieved by reducing dosage or correcting electrolyte imbalance.
Warning: Enteric coated potassium tablets have been implicated in small bowel lesions and should be used only when adequate dietary supplementation is not practical.

The Immune Globulins

In the July 1967 issue of MINNESOTA MEDICINE* is a comprehensive review of the knowledge which has been gained within the past 15 years on the subject of immunoglobulins. Today the well equipped clinical laboratory is able to recognize the various types of immunoglobulins, and this ability has become useful not only in the management of immune globulin disorders but of disorders of the protein metabolism in general.

The immune globulins are a distinctive group of proteins. Their electrophoretic mobility at pH 8.6 is slower than that of other serum proteins. They contain light chains within their molecule, which lack methionine as well as carbohydrate components. These qualities, particularly the absence of carbohydrates, appear to account for their peculiar type of solubility which was recognized in 1847 by Henry Bence Jones. This solubility factor has been used in the diagnostic test for light chain proteins small enough to traverse the glomerular filter and appear in the urine. To this day they bear the name of Henry Bence Jones. Carbohydrates, particularly sialic acid, appear to be involved in the mechanism of solubility of proteins[1].

If light chains can be produced in excess, so might heavy chains. This was indeed reported three years ago by Franklin and associates[2]. A protein of the molecular weight of 53,000 appeared in the serum as well as in the urine of Franklin's patients. No additional cases of heavy-chain disease have turned up since that time, in spite of diligent search by investigators here and abroad.

The spectacular findings of deficiency states of immunoglobulins have lent considerable impetus to the search for deficiency states of proteins outside the small group of immunoglobulins. Complete absence of serum albumin was encountered by Bennhold[3] in two otherwise healthy adult siblings. Additional cases have been discovered since. This recessively hereditary defect must worry physiologists considerably since these patients have only minimal or no edema in spite of absence of albumin and the finding of oncotic† pressures which are barely one half of the normal level.

It was only a matter of time before deficiencies or absence of other plasma protein components were discovered. The deficiency of antitrypsin, an α_1-globulin, appears to be associated with obstructive pulmonary disease[4]. Deficiency states of thyroxin binding globulin[5] and cortisol binding globulin[6], both α_1-globulins, have also been recognized. Deficiency of ceruleoplasmin, (an α_2-globulin) in Wilson's disease is well known. Haptoglobin deficiency has been recognized and described repeatedly[7,8].

Transferrin deficiency has been encountered on at least two occasions[9,10]. As might be expected, this abnormality presented itself as a refractory iron deficiency anemia. Afibrinogenemia with resultant blood clotting problems is a well established entity.

Though the list is not complete, one can readily appreciate the stimulus which the investigation of immunoglobulins has given to the study of proteins in general. The accumulating information will necessarily elucidate further important facets of human metabolism in health and disease.

Surgery for Otosclerosis *

THE SURGICAL treatment of otosclerosis offers prospects of restorative results of a very high order. Throughout the history of surgery, two things have been uppermost in the thinking and philosophy of the surgeon: the elimination of disease and the restoration of useful function. Surgery for otosclerosis is in the second category. The operation makes no attempt to eliminate all of the diseased tissue. The principle of the operation is to provide a detour around the diseased structures so that vibrations can again reach the nerve endings of the inner ear.

Sound reaches the ear as vibration in air. These vibrations enter the external auditory canal where they set the tympanic membrane into motion. This motion is transmitted through the chain of auditory ossicles to the fluid surrounding the sensory hair cells in the inner ear. Because fluid is incompressible the vibration must travel through the inner-ear fluid with a wave motion. This requires two openings in the bony walls of the cochlea. The first exists at the oval window into which the footplate of the stapes fits. The second exists at the round window, where a thin membrane allows the energy of the vibration to escape. Blocking of either window will create the symptoms of a conductive or mechanical hearing loss. Blocking of both windows creates the symptoms of a neural hearing loss.

Otosclerosis most often involves the region of the footplate of the stapes, obliterating the joint between the otic capsule and the stapes and thus interfering with transmission of sound. Restoration of a movable system effectively restores hearing. Less often, otosclerosis involves the bony wall of the otic capsule overlying the cochlea. In this instance, direct damage is done to the nerve with loss of nerve function. This type of hearing loss is not favorably influenced by surgical treatment. Otosclerosis rarely closes the round window to the cochlea; in this circumstance, improvement by surgical treatment has been reported in a few cases, although the prospect of improvement is limited.

At the present time the surgical treatment of otosclerosis may be compared with cataract surgery as a means of improving one of the special senses. The operation may now be done with a high degree of success but not without a small risk of further damage. Fortunately, if the operation is done on the ear with poorer hearing, the patient's handicap is not usually increased by an unsuccessful operation. Operation is not advised when it must be done on the only ear with hearing. Patient response to an operation which restores a wanted function is extremely gratifying. The patient whose hearing is restored after years of impairment is much more profuse in his expression of appreciation than is the patient who has been relieved of annoying symptoms or of risk by an operation on the mastoid.

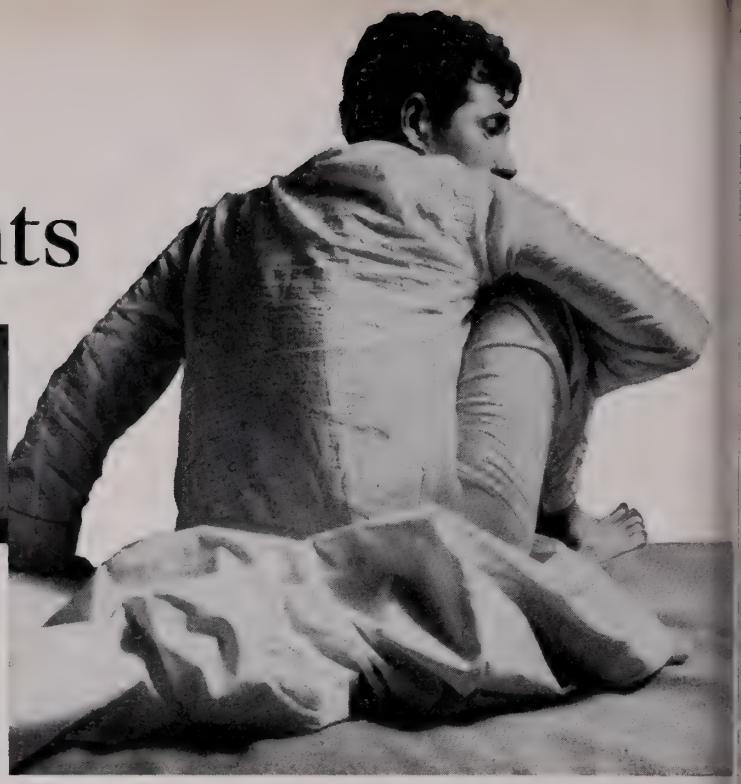
Polyhydramnios *



POLYHYDRAMNIOS is a rare but significant complication of pregnancy in which there is an excessive accumulation of amniotic fluid within the uterus. Most obstetricians consider an amniotic fluid volume of more than 2,000 ml. to represent polyhydramnios; the condition is classified as mild, moderate, or severe. Chronic polyhydramnios, which usually becomes detectable over a period of many days or even weeks, occurs once in approximately every 175 deliveries. The acute variety of the disease, which develops in a few days, is even more rare, occurring only once in about 12,000 deliveries.

The cause of polyhydramnios continues to be poorly understood. No abnormalities can be detected in the membrane of the amniotic sac

Open-eyed nights

Too tense to sleep...too tired to get up. **Early to bed, late to rise, and not much sleep at that, the patient with severe psychic tension is understandably tired. His tensions and overreactions to the day's stresses may interfere with proper sleep, and his inability to face the day's activities can produce an ever-worsening pattern. By relieving psychic tension, Valium® (diazepam) facilitates sleep, particularly with an h.s. dose. In many patients, the usefulness of Valium has been demonstrated in relieving psychic tension alone or with secondary depressive symptoms. Valium is generally well tolerated and, with proper maintenance dosage, usually does not unduly impair mental acuity or ability.**

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in: skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders; athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindications: Known hypersensitivity to drug; children under 6 months of age; acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in treatment of psychotic patients, and should not be employed in lieu of appropriate treatment. As with most CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increase in dosage of standard anticonvulsant medication; abrupt withdrawal in such cases may also be associated with temporary increase in frequency and/or severity of seizures. Advise patients against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance. Keep addiction-prone individuals (such as drug addicts or alcoholics) under careful surveillance because of their predisposition to habituation and dependence. Use of any drug in pregnancy, lactation or in women of childbearing age requires that potential benefit be weighed against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, carefully consider individual pharmacologic effects—particularly with known compounds which may potentiate action of Valium (diazepam), such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. Employ usual precautions in the severely depressed or in those with latent depression; suicidal tendencies may be present and protective measures necessary. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation (initially 2 to 2½ mg once or twice daily, increasing gradually as needed or tolerated).

Adverse Reactions: Side effects most commonly reported: drowsiness, fatigue and ataxia. Infrequently encountered: confusion, constipation, depression, diplopia, dysarthria, headache, hypotension, incontinence, jaundice, changes in libido, nausea, changes in salivation, skin rash, slurred speech, tremor, urinary retention, vertigo and blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances and stimulation have been reported; should these occur, use of the drug should be discontinued. Because of isolated reports of neutropenia and jaundice, periodic blood counts and liver function tests are advisable during long-term therapy. Minor changes in EEG patterns (low-voltage fast activity) observed during and after therapy and are of no known significance.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 50, 100 and 500.

ROCHE® LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

Valium® (diazepam)

useful for the relief of psychic tension, alone or with associated depressive symptoms

or in the contents of the fluid. Indeed, even the intra-amniotic fluid pressure is usually recorded as normal in patients with polyhydramnios. When the fetus has a major central nervous system anomaly, such as anencephalia* or spina bifida, it is speculated that the exposed meninges contribute an excessive amount of cerebrospinal fluid to the amniotic fluid. Fetal central nervous system anomalies are also thought to interfere with fetal swallowing of amniotic fluid and may at times cause excessive fetal urination and congenital gastrointestinal defects of the fetus, such as esophageal or duodenal atresia: factors that contribute to poor resorption of amniotic fluid, and can thus lead to polyhydramnios. Placental vascular system anastomoses between the two fetal circulations are thought to be the principal cause for the increased incidence of polyhydramnios in twin pregnancies. Many consider the chronic fetal anoxia sometimes seen in hydropic infants and infants of diabetic mothers to be the main reason for the increased incidence of polyhydramnios seen in such cases.

If the roentgenogram reveals a fetal congenital anomaly that is incompatible with life (such as anencephalia), induction of labor by amniotomy is indicated. When no major fetal anomaly is found on roentgenologic evaluation, symptomatic treatment and observation are indicated until the fetus reaches viable size (35 to 36 weeks' gestation). If polyhydramnios is severe, hospitalization is best. When respiratory distress is present, elevation of the head of the bed may be required, or the patient may have to sit up in a chair to be comfortable. Diuretics and special diets have been of no help in decreasing the excessive intrauterine accumulation of fluid. As the fetus matures, a repeat roentgenogram may detect an anomaly that was previously missed. In an effort to find the cause of the polyhydramnios, the mother's blood should be checked for irregular antibodies, and the presence of diabetes mellitus should be ruled out.

If the polyhydramnios becomes severe, causing marked maternal respiratory or cardiac embarrassment, before the apparently normal fetus reaches viable size, transabdominal amniotomy is indicated. The placenta should be localized so that it may be avoided and then, with sterile technique, 500 ml. of amniotic fluid may be slowly withdrawn through an 18-gauge spinal needle. This procedure may be repeated daily if necessary. Unfortunately, the withdrawal of the large amount of fluid necessary to give the patient symptomatic relief commonly leads to the onset of labor.

If the pregnancy can be continued until the fetus reaches viable size, labor may then be induced by a transcervical amniotomy with slow release of the amniotic fluid. Because of the dangers of placental abruption and postpartum hemorrhage due to uterine atony, crossmatched blood should be available for transfusion and an intravenous needle should be in place during the amniotomy and labor.

Approximately 25% of the infants delivered from patients with polyhydramnios will have major congenital anomalies incompatible with life. The most common of these anomalies are of the central nervous system, with anencephalia the most frequent. Gastrointestinal system defects, such as esophageal and duodenal atresia, are the next most common but are relatively rare. Circulatory anomalies, hydrops fetalis, and many miscellaneous defects account for the remainder.

Because of other obstetric complications, such as prematurity, prolapse of the umbilical cord, difficulties with infants born of diabetic mothers, and erythroblastosis fetalis, the overall perinatal loss with polyhydramnios is approximately 50%.

A complication of pregnancy, such as polyhydramnios, which is associated with a 50% perinatal loss is certainly significant. For an infant born to a mother with polyhydramnios, the prognosis is guarded until the presence of serious congenital anomalies has been ruled out and until the infant has survived the first days of life.

The basic problem in polyhydramnios is not how to manage the pregnancy associated with excessive amniotic fluid but rather how to prevent the abnormalities that cause such an excessive accumulation of fluid. Unfortunately, no prompt solution to this problem is foreseen.

Neurogenic Tumors of the Head and Neck*

ALL TUMORS OF the head and neck region should be removed for diagnosis because of the high incidence of cancer occurring in this region. If the tumor is obviously inoperable, a specimen of tissue should be obtained for diagnosis. This can be done with a Silverman needle, but frequently the pathologist prefers a larger piece of tissue for study. For operable lesions the best practice is total excision of the mass for diagnosis preferably by fresh-frozen section technique. If further surgery is indicated (such as a radical neck dissection) it can be carried out at the time of the biopsy procedure—there is no better time to do it. In almost all instances the patient should be under general anesthesia which would permit proceeding ahead with definitive treatment.

If the surgeon practices in this way it is essential that the best preoperative diagnosis possible be established and discussed with the patient so that he is prepared for the necessary treatment whatever it might be. Although many types of lesion occur in the head and neck, it is often possible to establish the correct diagnosis by careful evaluation of the history, physical findings, and results of laboratory studies. All neck structures and the entire oral cavity and larynx must be carefully examined.

Neurogenic tumors usually have been present for a period of years, showing slow growth. They are occasionally painful or tender. They may be multiple. On physical examination the lesion is most often well encapsulated, fusiform in shape, rather rubbery-firm on palpation, and lying in the direction of a major nerve. Other unassociated lesions are usually absent. The greatest difficulty in diagnosing this lesion preoperatively comes from failure to consider it because of its infrequent occurrence.

The Editor's Soliloquy

Physicians in Glass Hospitals

Opposition to the Long Amendment*, by the Minnesota and other Medical Associations, can undoubtedly share credit for its defeat in the first session of the 90th Congress. The Amendment suggested a federal formulary to govern the use of drugs in federal health care programs. Senator Long has publicly stated that the formulary system has attained acceptance in many hospitals of the country and that to extend these same principles to the area of outpatient governmental programs should afford no inconvenience.

The Minnesota Medical Association has generally opposed legislation which would handicap the physician in discharging his responsibility to his patients. In view of the willingness with which many doctors accept the dictates of their own hospital formularies, which encourage drug substitutions, it seems paradoxical that Long's federal restrictions should have met with such vigorous opposition from the medical profession. Why can't they be consistent?

Surely the physician should be allowed complete freedom to discriminate between different brands of the same drug when treating the acutely ill patient. Whether or not the subtle variations claimed by different manufacturers make any difference, it should be the physician's privilege and his responsibility to discriminate. Still it is in many of their own hospitals where some physicians have permitted non-medical persons to decide which drugs are best for their patients by requiring them to abide by the hospital's formulary. This is in effect nothing more than a system of "cracker barrel" prescribing.

That the motives of these administrators and their economic arguments are fallacious is apparent when one considers that the *wrong* drug for any patient could actually increase the total cost of hospitalization by delaying recovery or necessitating the use of another more expensive prescription when the substitute drug was not effective.

The method now used in some hospitals, seeking to control drug use, is to have a "no substitution" block on the prescription blank. If the doctor does not check the space, substitution is assumed to be authorized. This would seem to constitute an act of delegating a medical discretion. Other hospital pharmacies using a more insidious approach to restricting drug usage merely refuse to stock items which they prejudge to be unnecessarily duplicative.

Regardless of the means by which drug substitution is "authorized," the matter of liability has not been clearly decided; but the position of the AMA is that no physician can legally delegate "medical discretion of judgment" to a non-physician, and therefore, cannot properly authorize substitution without specific permission.

If a patient were to suffer death or injury resulting from the use of a substitute drug under a formulary system, the attending physician, the hospital and the pharmacist would share liability. It is possible, also, even with generic prescribing, that the physician can be held liable if the plaintiff is able to show a difference in therapeutic properties of drugs which fall under the same generic name. From the viewpoint of possible legal liability, drugs from trusted manufacturers whose resources may adequately cover lawsuits would seem to be preferable.

If physicians are to be successful in their efforts to preserve freedom from further bureaucratic regulation, their actions at home must be consistent with their arguments to the lawmakers.

Restrictions on drug prescribing must be actively opposed in the hospital as well as in Washington if physicians are to preserve the prerogatives of their profession and provide quality medical care to all Americans.

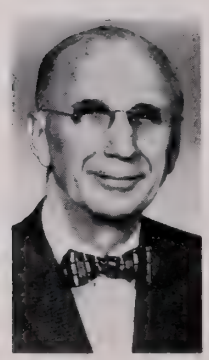
COR

Distinguished Service

Distinguished Service Award

John P. Medelman, M.D.

Dr. John P. Medelman was honored recently in Rochester by his physician colleagues as recipient of the 1968 Minnesota State Medical Association's Distinguished Service Award. The presentation was made at the annual banquet held during the Annual Meeting of the Association.



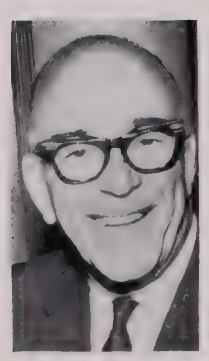
The award is the highest, bestowed by his colleagues, on a Minnesota physician who has made a notable contribution to medical science and the work of the Association. The recipient is selected by a committee of the Minnesota State Medical Association Council.

Dr. Medelman, born on a farm near Devils Lake, North Dakota, received his medical education at Rush Medical College in Chicago. He came to Minnesota, and did post graduate work and trained in Roentgenology. He has served on the staff of St. Joseph's Hospital for over 30 years, ultimately as director of the Hospital's school of X-ray technology and planner of its cobalt section.

Active in the Association, he has served as chairman of various committees and as a council member. He was state president in 1964 and is currently an alternate delegate to the AMA.

Dr. Medelman was a member of the State Board of Medical Examiners and served as its secretary for many years. He is a past president of the American Roentgen Ray Society and a member of the American Board of Radiology.

Citations of Merit

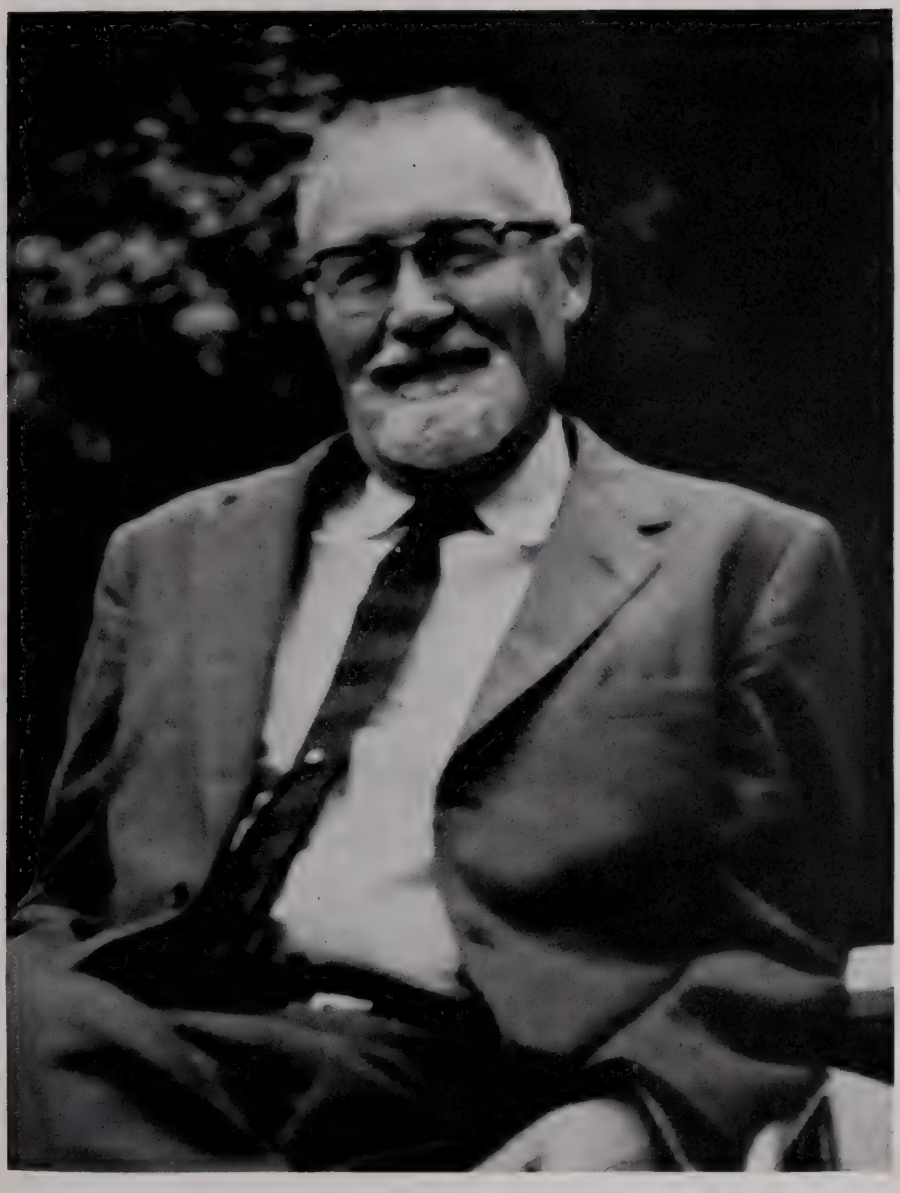


Harold S. Diehl, M.D.

Two special citations of merit were awarded to Dr. Harold S. Diehl and Dr. Ejvind P. Fenger.

Dr. Diehl, medical educator and administrator, was Dean of Medical Sciences at the University of Minnesota from 1935 to 1958. Upon his retirement from the University he became director of research for the American Cancer Society.

Dr. Fenger worked toward Minnesota's tuberculosis control for over 30 years. He was medical director of Glen Lake Sanitorium and is now serving as Director of Tuberculosis Services of Minnesota. Recently Dr. Fenger was named to the American Thoracic Society. This is an honor bestowed on individuals with a high achievement and signal contributions in the field of tuberculosis or other respiratory diseases.



Ejvind P. Fenger, M.D.

Scientific Exhibit Award

A medal for the outstanding scientific exhibit at the Minnesota State Medical Association's annual meeting was presented by the Southern Minnesota Medical Association to Doctors N. K. Jensen, W. R. Schmidt, J. J. Garamella, M. F. Lynch, A. M. Bilgutay and W. D. Kelly of Minneapolis. The exhibit's title was "Cardio-Thoracic Surgery."

Senior Educator

Reynold A. Jensen, M.D.

On July 1, 1968, Dr. Reynold A. Jensen will resign as Medical Director of the Division of Child Psychiatry, Department of Psychiatry and Neurology at the University of Minnesota, a post he has held since 1952. His decision to be relieved of the administrative responsibilities of the Division of Child Psychiatry was not easy, but it will provide him the opportunity to explore the area of communication during a sabbatical leave, a subject which has been of great interest and concern over the years.

Dr. Jensen's association with the University of Minnesota Medical School dates to 1935, when he graduated from that School. During this time, he has participated in the growth of child psychiatry there. This work culminated in 1952 when an inpatient children's unit was established. No one

single person in the state of Minnesota has been so clearly associated with the training of physicians in the specialty of child psychiatry, as well as in the teaching of student child psychiatry.

Teaching is Reynold Jensen's greatest love. He is never happier than when he has had a good seminar, supervisory hour, lecture. Also he enjoys running into a former student, who recalls how much he learned from Dr. Jensen.

He is a native of Sleepy Eye, Minnesota, where he graduated from high school in 1920. In 1925 he received a degree from the River Falls State Normal School, River Falls, Wisconsin; in 1963 that college awarded him its "Distinguished Alumnus Award." His M.D. Degree he received from the University of Minnesota Medical School in 1935. The years between 1925 and 1935 were spent in various jobs. He was YMCA secretary of the Milwaukee YMCA, 1925-1926, and director of religious education for the Congregational Church in Milwaukee, from 1926 to 1929. Before he joined the University of Minnesota faculty, Dr. Jensen served as an associate resident in medicine at the Strong Memorial Hospital in Rochester, New York, as a Rockefeller Fellow in Psychiatry at the Institute of Pennsylvania Hospitals, and as a Commonwealth Fellow in Child Guidance at the Judge Baker Guidance Center in Boston, Massachusetts.

Returning to the University in 1938, he was appointed an instructor in psychiatry and pediatrics. In the ensuing years, his interest and enthusiasm for child psychiatry was combined with an abiding concern in the total life of the University of Minnesota. He has never limited his interests to the Medical School, but has always identified himself with the goals and purposes of the University at large.

An important part of Jens' life has been his wife, Lillian, daughter of a Sleepy Eye, Minnesota, farmer. She attended Sleepy Eye High School before entering the University. They were married in the middle of his internship. Lil specialized in mathematics, economics and psychology at the University of Minnesota, then decided on editing. She is currently active in free lance work and technical writing, particularly for the American Hospital Association.

In recent years, Dr. Jensen has become interested in the problems of aging; since 1963 he has been a member of the Community Health and Welfare Councils Committee on Aging. He is also a member of the Community Health and Welfare Council Board of Directors, the Economic Opportunity Committee, and he has chaired a committee reviewing services to the elderly in public housing.

His special interest has been the retarded child. He has served on numerous state and national level boards and committees on retardation and mental health. He has been on the scientific advisory board of the National Association for Retarded Children. He is also a member of the Minnesota branch of the American Civil Liberties Union. For a number of years he has served as an associate editor in the area of child psychiatry for Minnesota Medicine, the official journal of the State Medical Association.

A man's life and contribution is only poorly reflected in the recitation of his numerous memberships and organizations. Far more important is his personal warmth and enthusiasm for teaching and his unselfish devotion to the cause of children in the advancement of the speciality of child psychiatry.

Now . . . a new
alternate salicylate product
from Warren-Teed

Magan®
(magnesium salicylate, W-T)

particularly offered for the management
of those chronic arthritic and rheumatic
patients with gastrointestinal intolerance
to aspirin and other salicylates

magan®

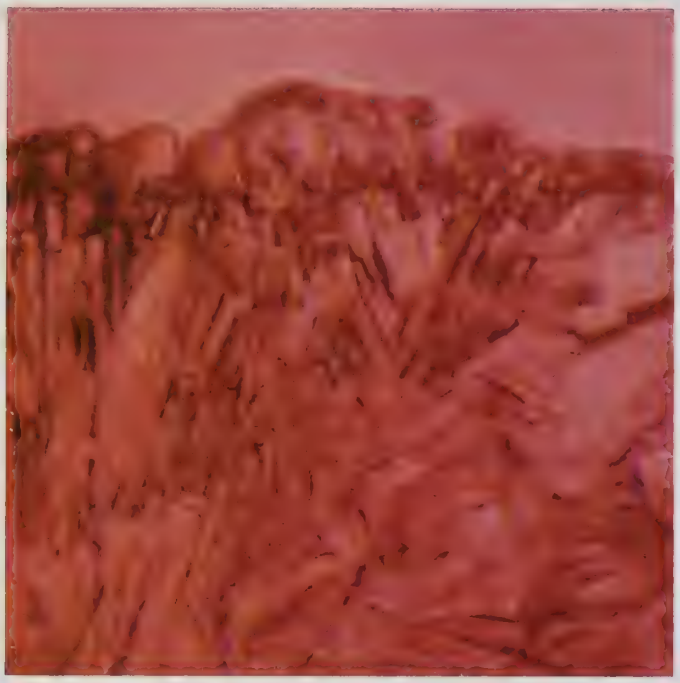
an alternate salicylate

pain relief comparable to aspirin

Magan may provide effective salicylate therapy for a substantial number of your patients who cannot tolerate other salicylates because of gastrointestinal irritation.

Magnesium salicylate is recognized as a safe and effective alternate to aspirin. A controlled clinical study showed Magan to be not significantly different from aspirin as an analgesic in the treatment of arthritic patients.[1]

Reports from a private practice experience study indicate that Magan was tolerated by a high percentage of patients judged by their physicians to be unable to take aspirin or other salicylates due to gastrointestinal intolerance.[2]



1. Stern, S.B.: Med. Times, Oct. 1967
2. Reports on 1200 patients, data in files, Warren-Teed Pharmaceuticals, Inc. 1966

(See next page for prescribing information)

A different salicylate structure—
with no coating, no buffering
and it is sodium free

magan®
(Magnesium Salicylate, W-T)

microphotograph of magnesium salicylate crystals

Composition: Each orange-colored compressed tablet contains 5 grains (approximately 325 mg.) of magnesium salicylate, W-T (salicylic acid equivalent 75%).

Actions, Indications, Uses: The analgesic, anti-inflammatory, and antipyretic effects of MAGAN are similar to those of aspirin and other salicylates. Accordingly, MAGAN is indicated for the treatment of rheumatoid arthritis, osteoarthritis, nonarticular rheumatism such as bursitis, painful-shoulder syndrome, tendosynovitis, fibrositis, and other musculoskeletal disorders. The drug is also useful for the symptomatic relief of pain, aches, and discomfort of headache, neuralgia, minor injuries, dysmenorrhea, common cold and other minor infections of the respiratory tract. MAGAN (Magnesium Salicylate) may be tolerated by some persons intolerant to aspirin by reason of gastrointestinal irritation.

Contraindications: Because of the danger of hypermagnesemia, MAGAN is contraindicated in cases involving advanced chronic renal insufficiency. MAGAN, as other salicylates, may counteract the effect of uricosuric agents, and should not be prescribed for patients on such drugs.

Warning: As with all salicylates, high dosages of MAGAN should be avoided entirely or administered with caution to patients with liver damage, preexisting hypoprothrombinemia, vitamin K deficiency, and before surgery.

Adverse Reactions and Precautions: The same precautions applicable to salicylate therapy in general should be followed in prescribing MAGAN. Appropriate precautions should be taken in prescribing MAGAN for persons known to be sensitive to salicylates. If reaction develops, drug should be discontinued. Dosages of anticoagulants should be reduced with the administration of high dosage levels of MAGAN. *Impaired Renal Function:* Appropriate precautions should be taken in administering MAGAN to patients with any impairment of renal function including discontinuing other drugs containing magnesium and monitoring serum magnesium levels particulariy if dosage levels of MAGAN are high. *Salicylate Poisoning:* Symptoms of salicylism, resulting from high doses of MAGAN, can be expected to resemble closely in character and intensity those associated with aspirin poisoning. These range from dizziness, drowsiness and ringing in the ears to vertigo, convulsions, coma and hypokalemia. Salicylate poisoning can be treated by intravenous fluids with sodium bicarbonate or lactate and potassium supplementation. In very severe cases, hemodialysis may be necessary. Vitamin K, 5-20 mg. orally or slowly i.v., usually restores the prothrombin time to normal.

Dosage: Adults 1 or 2 tablets every 4 hours as required with a full glass of water. In arthritis and other rheumatic conditions, higher doses may be used at the discretion of the physician. The experience with MAGAN in children is limited. The drug should not be used, therefore, for patients below 12 years until indications for use and dosage have been established.

How Supplied: Bottles of 250 and 1000 tablets.

Breast Cancer

QUESTION: What is the incidence of cancer in the opposite breast with primary operable cancer of the first breast?

ANSWER: The overall incidence of primary cancer in the second breast has been stated to range between 7.5% and 10%, which is about five times greater than in the general population. Urban recently reported on random simultaneous biopsies of the opposite breast in 159 women with primary operable cancers of the first breast. Cancer of the second breast was detected in 19.5% of the cases in that series.

Harold D. Kletschka, M.D.
Houston, Texas

Acute Altitude Sickness

QUESTION: To what pathologic changes are the pulmonary symptoms of acute altitude sickness attributable? Is pulmonary edema a factor?

ANSWER: Individuals rapidly transported to altitudes over 10,000 feet above sea level develop pulmonary symptoms which are well known. This disease entity is referred to variously as acute altitude sickness, high altitude pulmonary edema, mountain sickness, or soroche. It is generally agreed the symptoms are due to hypoxia. These symptoms may occur even in individuals thoroughly acclimatized to living in high altitudes on returning to mountainous areas, for example, after staying at sea level for one to three weeks.

Pulmonary edema may occur in such patients, but the underlying physiopathologic alterations are not clearly established. Acute left ventricular failure or pulmonary venous constriction have been suggested as causative factors.

Treatment in such cases consists of removing the patient to a lower elevation, bed rest, and continuous oxygen administration.

Solitary Lytic Skull Lesion in a Thirteen-Year-Old Male

THIS THIRTEEN-year-old white male was in good health until six weeks prior to admission, at which time he noted the onset of occipital headaches. These occurred occasionally in the morning but were most severe in the evening. There was no nausea or vomiting, and some relief was obtained with salicylates.

Approximately two weeks after the onset of the headaches, the patient noted a tender lump in the occipital area. The bump increased slowly in size during the next four weeks.

Radiographic examination of the skull revealed a destructive punched-out lesion (Arrow, Figure) of the occipital bone. Both the inner and the outer tables of the skull are visible. The border of the lesion is non-sclerotic. A skeletal survey was otherwise negative.

What is your diagnosis? (See next page.)

Figure

Diagnosis. Histiocytosis X (Eosinophilic Granuloma)

The differential diagnosis includes:

1. Cholesteatoma
2. Hemangioma
3. Histiocytosis X (Eosinophilic Granuloma)

Histiocytosis X is a disease entity which includes eosinophilic granuloma, Letterer-Siwe disease, and Hand-Schüler-Christian disease, all of which are phases of a single entity.

Primarily histiocytosis X is a disease of the reticulum cells. Eosinophilic granuloma is the chronic form of the disease and is characterized microscopically by the presence of eosinophilis and histiocytes with areas of necrosis.

Eosinophilic granuloma occurs most commonly between the ages of three and ten. Although rare after fifteen years of age, the disease has been reported in the sixth decade of life. Solitary painful bone lesions are the usual finding, although multiple bones may be involved. Rarely are visceral organs involved.

Biopsy is necessary to make the diagnosis. The prognosis is excellent. Although the lesions tend to heal spontaneously, radiation therapy is the treatment of choice. As little as 50 rads has been reported to eliminate the symptoms within a few hours. The usual dose is 500 to 1000 rads, given in three to four treatments.

The truth is incontrovertible. Panic may resent it; ignorance may deride it; malice may distort it, but there it is.—Winston Churchill, 1915

Fracture Conference

Ununited Fractures of Lower Third of Tibia*

Dr. Mark B. Coventry:†

We are going to talk about ununited fractures of the lower third of the tibia.

Case 1

Dr. Edwin L. Laurnen:‡

The first case is that of a 40-year-old housewife whose history dates back to 1952 when, at age 25, she sustained a fracture of her right tibia and fibula while skiing. Her home physician treated this by open reduction and plate fixation. The fracture was complicated by infection at this time in 1952 and she had numerous sequestrectomies§ and other treatment in order to curb the infection. However, she seemed to get along fairly well, and resumed her skiing until April 1959, when she refractured the tibia and fibula. The fracture was treated by grafting with autogenous iliac bone; but she continued to have pain and disability in the leg. Thus, when she was first seen here in April 1967, she had been having difficulty with this extremity for 15 years. The roentgenographic appearance of the leg is shown in Figure 1-A and B. Clinically, she had posterior bowing of 30° and, not apparent in the roentgenograms, 30° of internal tibial torsion.

Dr. Coventry:

On the lateral roentgenogram note the degenerative change at the posterior one third of the ankle joint. Dr. P. J. Kelly and I have been especially interested in this phenomenon. The marked posterior bowing produces these degenerative changes in the posterior aspect of the talotibial joint. Dr. Enneking is visiting here today, and we are going to start working him hard early this morning by asking him to comment on these patients before we tell you what we have done.

Dr. William F. Enneking:¶

Do you know whether the posterior angulation persists from her first injury or is this a shift?

Dr. Laurnen: I don't know for certain.

---

*Held January 15, 1968.

†Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota) and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

‡Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

§See Test Your Word Score Page 937.

¶Professor of Orthopedic Surgery, University of Florida, and visiting orthopedic professor at the Mayo Graduate School of Medicine, January 15 to 17, 1968.

Dr. Enneking: You don't know how much displacement there was on refracture?

Dr. Laurnen: No. The second fracture occurred in April 1959.

Dr. Coventry:
It is important to remember that she has a 30° internal torsion deformity of the distal tibial fragment. She walks very pigeon-toed. That doesn't show on these films.

Dr. Enneking: How long after the second injury was this film made?

Dr. Laurnen: Eight years.

Dr. Coventry: Her complaint now is deformity and pain?

Dr. Laurnen: Yes, and limb shortening.

Dr. Coventry: Is there any drainage now?

Dr. Laurnen: No.

Dr. Enneking: Obviously, from the standpoint of (1) activating her infection and (2) changing the relationship between the talus and fibula, it

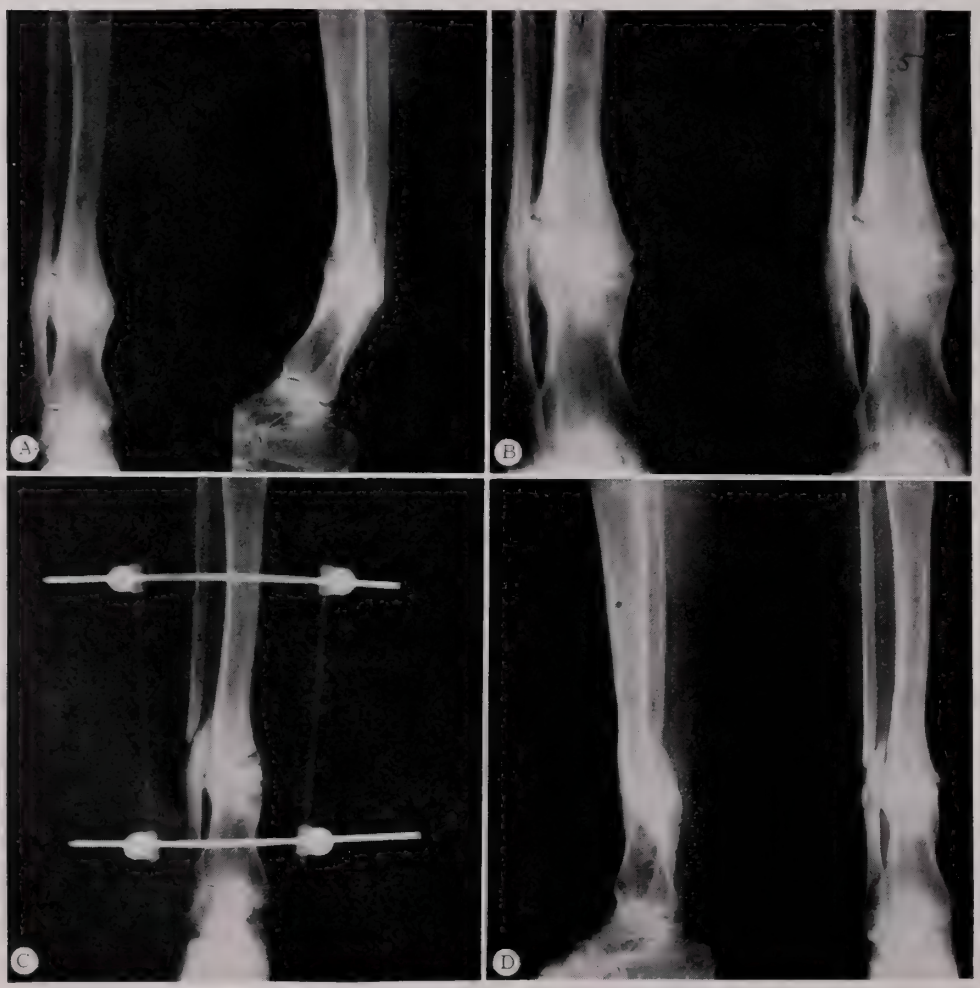

Fig. 1—*A*, Forty-year-old housewife with pain, deformity, and fibrous union of an old fracture. *B*, Anteroposterior tomograms of old fracture with fibrous union. *C*, Appearance after wedge-osteotomy correction of deformity, grafting, and incorporation of Roger Anderson apparatus. *D*, Five months after corrective operation and use of onlay grafts.

would be extremely hazardous to try to correct her deformity. As long as she isn't having drainage and significant pain, and if she would accept her deformity, I suspect I would probably let it go at that. If I had to try to correct it, I would probably try to make the correction a good distance from the old injury if she wasn't having drainage. I thought I saw a sequestrum on the tomogram.

Dr. Coventry: How long has she gone without drainage?

Dr. Laurnen: Several years.

Dr. Enneking: I think I would avoid operation if I could find any reasonable way to do so.

Dr. Coventry: She is a young mother and walks with a cane. She has much deformity.

Dr. Patrick J. Kelly:* Is there union or not?

Dr. Coventry: The fragments are ununited, but she has a rather firm fibrous union. Why don't you show Dr. Enneking what we did?

Dr. Laurnen:

In May 1967, shortly after she came, a wedge osteotomy was performed to correct this deformity (Figure 1-C). The base of the wedge was situated posteriorly and medially and two Steinmann pins were placed in the tibia, one proximally and one distally, and incorporated into the Roger Anderson apparatus with some compression. Use of these pins was continued for three months and then they were removed. The cast also was removed and she was placed in a short leg lacer brace. Five months after treatment she had union (Figure 1-D) and seemed to be having a satisfactory result from surgery. The fibula was osteotomized at the time the deformity was corrected.

Dr. Coventry:

She had no drainage. We used small sliver-like onlay grafts a la Phemister.[1,2] We took these from the valgus part of the pseudoarthrosis, that is, the adjacent bone, and laid them over the osteotomy site. One can't put too much bone in this area, as you know, because there is little soft tissue for coverage. There was quite a bit of scarring of the skin in addition. The posterior part of the tibiotalar joint should be noted. It seems to have opened up a bit and I think maybe it will last her a good while. She is walking without a cane and without torsional deformity. A letter received this week indicates that she now has full activity, no deformity, no pain, and a happy result.

Dr. Joseph M. Janes:† What is the cause of the calcification in the Achilles tendon?

Dr. Coventry:

I don't know whether that has resulted from partial rupture of the tendon or from direct trauma. Bony trabeculae are seen on close inspection, so I suppose it is heterotopic bone. Well, let's go to the next patient.

---

*Associate Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of of Minnesota), Rochester, Minnesota. Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

†Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota. Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

Case 2

Dr. Laurnen:

Our next patient is a 40-year-old man who also sustained a fracture of his right tibia and fibula while skiing in February 1966. This was treated in his home community by open reduction and insertion of two Rush pins two weeks after injury. Four months after injury the pins were removed and a cast was reapplied for an additional two and a half months. Then he resumed unrestricted weight-bearing six and a half months after fracture. However, he continued to have disability with this extremity and came here 15 months after injury. The roentgenographic appearance of the fracture at that time is shown in Figure 2-A and B.

Dr. Coventry:

Does anyone think this would be a good case, if seen initially, for intramedullary nail fixation? I don't see any show of hands. I would agree. The fracture is much too low and this may have contributed to the nonunion,

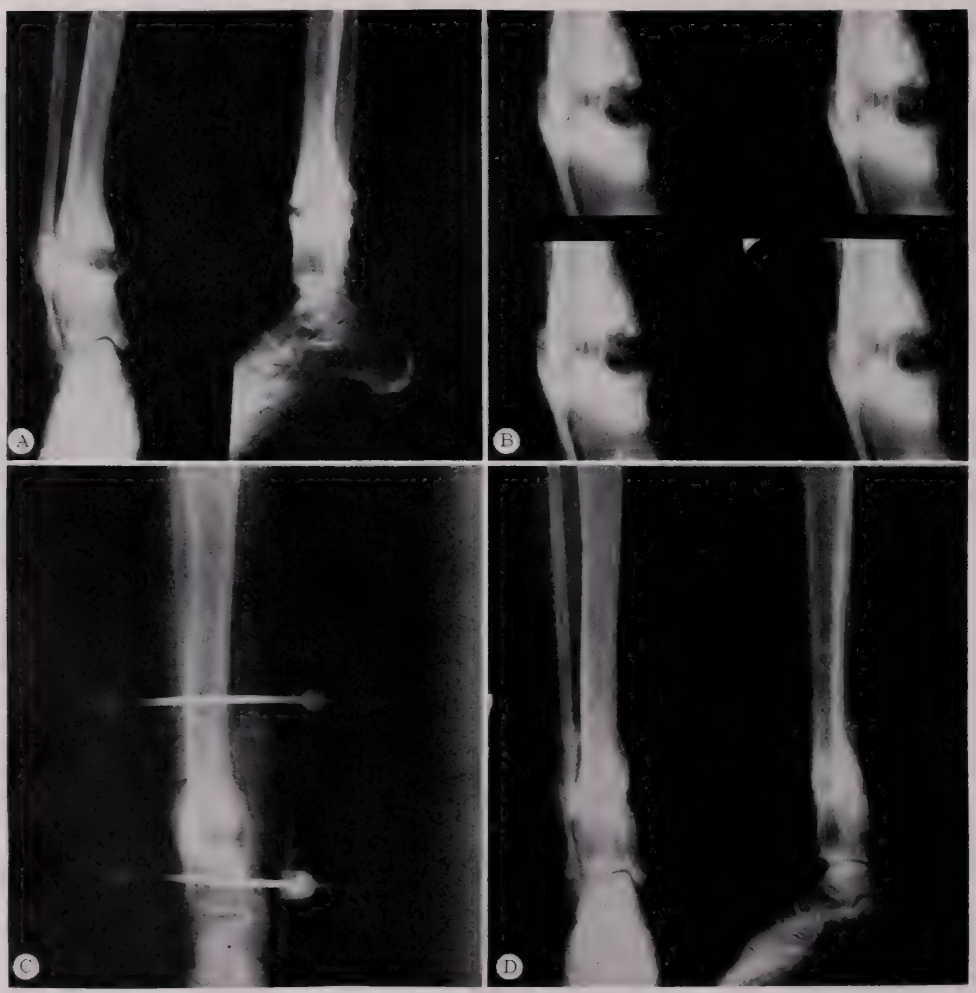

Fig. 2—*A*, Nonunion 15 months after injury. *B*, Anteroposterior tomograms showing nonunion prior to treatment at Mayo Clinic. *C*, Appearance after osteotomy and iliac onlay grafting, showing compression and fixation with Roger Anderson apparatus. *D*, Eight months after treatment of nonunion of tibia.

although we don't know for sure. Dr. Enneking has just come back from two days of skiing, so I thought we would introduce him to the problems of orthopedic practice in the northern part of the country, as opposed to Florida! I suppose you do get water-skiing injuries down there?

Dr. Enneking: They don't break their tibias, though.

Dr. Coventry: Just their necks?

Dr. Enneking: They do that, but they also get anterior dislocations of the hip.

Dr. Coventry: Are there any comments on this fracture?

Dr. Kelly: Is his foot fixed in that amount of equinus deformity?

Dr. Coventry: No, he has a good movable ankle and a normal-looking foot.

Dr. Kelly: And as far as we know, it is not infected?

Dr. Coventry: It is not infected.

Fig. 3—*A* and *B*, Fifty-three-year-old truck driver 1 year after primary open reduction complicated by infection. *C* and *D*, Appearance after correction of deformity and application of Roger Anderson apparatus. *E*, Apparatus as it appeared clinically. *F*, Fourteen months after treatment of nonunion.

Dr. Enneking:

I think I probably would have done an osteotomy of the fibula to align the fracture and would have applied an onlay graft, probably without any internal fixation.

Dr. Laurnen:

Again two pins connected with a Roger Anderson apparatus were used, with an autogenous onlay iliac graft (Figure 2-C). Two months later the Steinmann pins were removed and he was placed in a cast for an additional two months. After four months of treatment the cast was removed. He was placed in a short leg lacer brace with full weight-bearing for two months. The healed tibia is shown in Figure 2-D.

Dr. Coventry:

Again one can see small onlay bone grafts on the roentgenogram. One doesn't have room for much grafting here, and the grafts are put on in barrel-stave fashion. This man is sales manager of a ski company, so it is important to get him back to skiing! He will be going back, I think, later this year.

Two of the residents asked about the external bars of the Roger Anderson apparatus. As you know, Haynes, Stader, and Anderson developed, before World War II, a method of holding fractures externally, without plaster. As a matter of historical interest we will present some data on a patient who was operated on in 1954 for osteomyelitis and nonunion following compound fracture of the tibia and fibula.

Case 3

Dr. Laurnen:

This man was 53 years old when injured. He was a truck driver who, in November 1955, was in a truck accident and sustained multiple injuries involving primarily the lower extremity and also including a fracture-dislocation of the pelvis and hip. He was treated first in his home community and came to the Mayo Clinic for treatment one year after the accident, with the roentgenograms illustrated in Figure 3-A and B.

Dr. Coventry:

He had a complete sciatic palsy on the left and partial sciatic palsy on the right. His urinary tract was functioning fairly well. We thought he would walk again, so we made every effort to correct the infection and nonunion of the tibia.

Dr. Laurnen:

The fractured tibia and fibula originally had been opened and subsequently had become infected. Before he came here several attempts had been made to eradicate the infection. We applied the Roger Anderson apparatus illustrated in Figure 3-C and D. We did one additional sequestrectomy and three weeks later applied only autogenous iliac grafts. Figure 3-E illustrates the apparatus as it appears clinically.

Dr. Coventry:

This treatment was given before the advent of suction-drainage treatment or tubal instillation of antibiotics. Dimethoxyphenyl penicillin (Staphcillin) was not available either. But somehow or other, healing eventually occurred, mostly because of thorough debridement and firm fixation.

Dr. Laurnen:

The Roger Anderson apparatus was left on for three months. A roentgenogram (Figure 3-F) taken 14 months after treatment by this method revealed solid union without evidence of infection.

Dr. Coventry:

The patient returned two months ago with a minor flare-up of infection. We did a sequestrectomy and put in tubes for irrigation-suction and left them in three weeks. This was combined with antibiotic therapy for his *Staphylococcus aureus* infection.

This method of external fixation is occasionally still indicated, and we must all be aware that it is available and helpful in extreme circumstances.

Dr. Kelly:

Was it King[3] that used this same treatment almost routinely for fracture of the tibia? He presented a paper at the meeting of the American Academy of Orthopaedic Surgeons. He sharpened off the end of the tibia, impaled it into the end of the distal part, and then, I think, he used rubber bands to hold the pins together. It sounds Rube Goldberg-like, but it worked fairly well for him. It would be appropriate for a fractured tibia that one wished to treat without the use of metal and that one wanted to stabilize.

Dr. Coventry:

None of these three patients had a fracture that was suitable for compression with internal fixation. There was a bulbous change at the fracture site and we simply could not apply plates because of this bulk. So we used the pins to create and maintain compression. Alignment was maintained with plaster, and the strength of the entire fixation was enhanced by incorporation of the pins and compressing rods in plaster.

Dr. Ronald L. Linscheid:*

The Roger Anderson apparatus is helpful in another circumstance, namely when a fracture of the tibia is accompanied by skin loss, and a skin graft is necessary.

Dr. Coventry:

It is very helpful there. Otherwise, one is working through a hole in a cast, which is not always satisfactory.

Dr. Enneking: How rigid is that fixation?

Dr. Coventry:

It is amazingly rigid, if you follow the basic principles of using enough pins and then getting an oblique cross bar which controls torsion. You simply can't move it—you can pick it up and shake it and it remains rigid.

Dr. Kelly: It was a veterinary apparatus to begin with, wasn't it?

Dr. Coventry:

Well, Stader was a veterinarian, but Haynes, who developed it, was not. I don't know who gets priority.

Dr. Enneking:

We decided to try making a movie to represent a human fracture by taking a roentgenogram of a dog's fracture every hour and then exposing these roentgenograms a few frames at a time so that we could obtain an effect somewhat like that of riffling through an old comic book. A fellow in Ar-

*Instructor in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota) and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

kansas had made one and it was effective. So one of our fellows flew to Washington and got a dog and put all the "stuff" on it. Even though the dog was restrained and his body was as immobile as we could make it with drugs, every time we exposed an x-ray film the structures had changed just a little so that when we made the movie the appearance was that of a bunch of spaghetti moving around. Our purpose in doing this was to determine whether or not this type of fixation gave absolute immobilization of a fracture and also to determine whether motion, if it did occur, impeded union. Our attempts to do these things failed, but the fracture in the dog did heal nevertheless.

Dr. Coventry:

We have a fair amount of stability by the time we cut these bone ends off and have cortical bone in contact with cortical bone. This gives an inherent, built-in stability, and I think that point is important in the three fractures we have just shown.

Conclusion

These three cases represent the problems associated with long-standing nonunion and sometimes infection of fractures of the tibia. As you can see, alignment, or rather malalignment, is a factor in subsequent degenerative changes in the adjacent joints and surely causes symptoms and produces cosmetic change. Inherent stability of the bones at the site of the corrective osteotomy, adequate fixation externally with pins, and control of infection are necessary to obtain a satisfactory result.

The Diploma Phantom

The diploma gives society a phantom guarantee and its holders phantom rights. The holder of a diploma passes officially for possessing knowledge . . . comes to believe that society owes him something. Never has a convention been created which is more unfortunate for every one—the state, the individual (and, in particular, culture).—Paul Valery

Dermatology

Sunlight Sensitivity

ECZEMA SOLARE (polymorphic light eruption) may develop at any age and usually lasts for many years. Physicians' interest in this disease is greater than before because the disorder is being recognized more readily than previously; however, with the use of new systemic medications, some of which are potential photosensitizers, the increased incidence of this disorder may be partially due to these drugs.

The severity of this disease may be due to many factors, such as duration of exposure, time of year, temperature, etc.; however, the amount of ultraviolet light exposure is the most important variable. The atmosphere scatters the shorter blue light (including the ultraviolet) which gives the sky its blue color. Over three fourths of the ultraviolet light reaching the skin comes from the blue sky and not directly from the sun.

In the spring the patient with cutaneous light sensitivity will be subjected to sufficient quanta of ultraviolet light to precipitate symptoms. The maximum amount of exposure is during June; thereafter the amount decreases, and most patients have little trouble with their disease after early fall, as the sun is close to the southern horizon and the sunlight must pass through a far greater mass of atmosphere than in summer. As a rule, the patients are free of their disease in the winter.

Figure

Generally, within minutes to several hours after the first major exposure to sunlight in the spring, patients experience tingling, burning, and itching on the exposed areas. In most patients the eruption may appear within three to six hours or as much as several days later and can vary from mild erythema to bullous lesions. Because of the protective effect of clothing, the borders of the dermatitis are usually sharp. The differential diagnosis includes lupus erythematosus, erythema multiforme, urticaria, porphyria, ragweed dermatitis, etc. If the condition is unrecognized, chronic erythema and lichenification result and may resemble other eczematous conditions such as atopic eczema, contact dermatitis, or seborrheic dermatitis. The eruption may even extend to those areas not usually exposed to sunlight.

In the treatment of the mild acute eruption, oral antihistamines and topical steroids are used; but if the eruption is extensive, a short course of systemic steroids may be warranted. However, long-term use of oral steroids for treatment or protection is to be avoided. While the eruption is present, further light exposure must be restricted; as the eruption subsides, additional protective measures are instituted.

The only dependable protection is for the patient to avoid that quantity of light exposure which precipitates symptoms. Many patients can tolerate some minutes to several hours of light exposure before eight to nine A.M. and after three to four P.M. To avoid the use of uncomfortable (protective) clothing in summer, one may use topical sunscreen lotions and creams; but the degree of protection is unpredictable, as none of these preparations is ideal. If they stick to the skin, they are usually greasy and prevent sweating; if water-soluble, sweating or bathing removes the protective layer of the sunscreen. In each patient the protective value of any sunscreen can be determined only by usage.

Automation and Medicine

Since the practice of medicine is essentially the computation of statistical probabilities I think there is little doubt that if all relevant information were stored in one place and made available for computation the accuracy and hence the quality of medical care would be greatly improved . . . The seasoned clinician enlarges his knowledge and improves his statistical calculations as he grows older . . . but most of his acquired information dies with him. The computer remains immortal . . .

This development will not encroach upon the time-honored duties and values of the physician . . . but he will be forced to think quantitatively about the information he obtains. This in itself will greatly increase the value of clinical data and will heighten the perceptions and analytical ability of the physician . . . his personality will remain a deciding factor in the therapeutic process, but he will no longer be forced to call upon his own memory for the complex assessment of the statistical probabilities of each diagnosis . . . Fortified with the vast knowledge of a computer he will more fully develop his own potential as a physician and as a human being.*

Book Reviews

The Love of Books, the Golden Key That Opens the Enchanted Door.—Andrew Lang

TREATMENT OF HEART DISEASE IN THE ADULT. By Rubin, I. L., Gross, H., Arbeit, S. R., and Hutcheon, D. E. Lea and Febiger, 1968. Philadelphia. 393 pages. Price unknown.

This work is the collaboration of three clinicians at the well known Montefiore hospital in the Bronx (the first three authors) and Hutcheon, in the department of pharmacology of the New Jersey College of Medicine. It is a valuable, authoritative handbook of treatment that will serve as a useful standard of what is being done in adult cardiac therapy in 1968. Particularly helpful are the precise tables and outlines of treatment for such common conditions as myocardial infarction and arrhythmias. No doubt many will object to specific features in an outline of therapy, but it is comforting to know that contained herein are the orders for a myocardial infarction from the pain to the pan to the perambulation.

This is a large book. It measures 9 by 11 inches: very close in size to the Merriam Webster unabridged dictionary—with which an invidious comparison may be made. "Treatment", exclusive of covers, is ¾ inch thick and contains 393 pages. A similar depth of dictionary contains 500 pages; but the serious criticism is that Webster can print over 100 three-column lines to each page compared to about 50 single column lines in the "Treatment" book. The conclusion is inescapable that "Treatment" is turgid. One could condone, even praise the thick glossy paper so inviting to the solution of difficult printing tasks such as x-ray reproduction. Some of the x-rays are indeed fine examples of the art of printing; but most are no better than one would expect on less weighty paper. The words are recommended. The paper, the size, the weight, and the illustrations are not.

The book would be more acceptable as a ¾-inch octavo for an intern's pocket.

ULTRASTRUCTURE OF NORMAL AND ABNORMAL SKIN. by Alvin S. Zelickson, 431 pp, 377 illus, $22.50, Philadelphia: Lea & Febiger, 1967.

This book presents a concise and well written survey of the field of electron microscopy. Its emphasis concerns the skin; however, the book should appeal to anyone who is interested in ultrastructure. The advances made and the knowledge accumulated in this aspect of histology have been rapid. It, therefore, becomes a necessity to have an authoritative reference source. This book fulfills that need.

Dr. Zelickson has enlisted highly competent coauthors, each an authority in his respective subject. The result is a well written and remarkably easy to read book on this technical subject. Basic principles concerning the instrument as well as the interpretation of cell ultrastructure are dealt with in the first part of the book. In the latter sections comprehensive coverage is given to more advanced aspects of cutaneous ultrastructure (abnormal as well as normal). As a result this book provides a ready access to much knowledge in this rapidly advancing field.

Willard C. Peterson, Jr., M.D.
Minneapolis, Minnesota

CARDIAC RADIOLOGY. Edward D. Dunne, 246 pages, Lea & Febiger, Philadelphia, 1967.

This book is based on the author's personal experience as a radiologic member of the cardiac team at St. Vincent's Hospital, Los Angeles. The topics discussed are limited to the valvular lesions and the common congenital anomalies, i.e., the sextal defects, patent ductus arteriosus, coarctation of aorta, pulmonary stenosis, and tetralogy of Fallot, with brief excursions into relevant associated lesions.

The sole emphasis of the book is on the findings presented by the routine plain films (the four cardiac views plus an overpenetrated anteroposterior view) and fluoroscopy. These are discussed in great detail and correlated with the results of catheterization, angiocardiography and surgery. The author stresses the importance of fluoroscopic examination, which he feels offers the greatest hope for improved radiologic diagnosis.

The illustrations are of very good quality. The bibliography is relatively small.

This work should be helpful to radiologists, cardiologists and their residents in search for a comprehensive and competent review of the basic roentgen diagnosis of the common cardiac diseases. Some may even be challenged to prove or disprove the value of cardiac fluoroscopy.

S. H. Tsai, M.D.
Minneapolis, Minnesota

In Appreciation

The Minnesota State Medical Association recognizes the valuable contribution made by our technical exhibitors to the success of our recent 115th Annual Meeting. We also recognize that their participation in future meetings is essential if we are to maintain our tradition of outstanding medical meetings. The firms listed below, through their participation in our 1968 meeting, have demonstrated their interest in the Minnesota State Medical Association and our Annual Meetings. We request that our members join us in expressing our sincere appreciation to these firms and their representatives. We believe that each and every member present at our Annual Meetings would find it beneficial to visit the uniformly informative exhibits that these firms provide.

JUDGE ANTIBIOTIC OINTMENTS HERE

Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Complete literature available on request from Professional Services Dept. PML.

New

Therapeutic breakthrough in non-narcotic control of the pain of

Tegretol®
carbamazepine

trigeminal neuralgia

Warning
Fatal cases of aplastic anemia have been reported following treatment with Tegretol. Agranulocytosis, thrombocytopenia and transitory leukopenia have also been observed.
Complete blood and platelet counts should be done prior to and at regular intervals during treatment with the drug (see recommendations under "Important Note and Precautions") to help in the early detection of serious bone marrow injury. Abnormalities in initial blood tests should rule out use of the drug. Also, patients should be made aware of such early toxic signs of a potential hematologic problem as fever, sore throat, mouth ulcers, easy bruising and petechial or purpuric hemorrhage. Should such signs appear, the patient should be advised to discontinue the drug and to report to the physician immediately.

Indication Tegretol is indicated in the treatment of the pain associated with true trigeminal neuralgia. It is not a simple analgesic and should never be administered for relief of trivial facial aches or pains.
Contraindication Do not use in those with a known sensitivity to any tricyclic compound or in those being treated with M.A.O.I. agents. As long a period as possible should elapse before using Tegretol in patients who have been treated with M.A.O.I.'s, with a minimum of 7 days. In such cases, initial dosage should be low and the patient's reaction to gradual increments closely observed.
Important Note and Precautions Familiarity with the clinical symptoms which lead to an accurate diagnosis of true trigeminal neuralgia and with the complete prescribing information, careful patient selection, a thorough examination before treatment and close patient supervision throughout the treatment period are essential to the safe and effective use of this drug.
Where feasible, Tegretol should not be used in conjunction with any potent drug which may increase the possibility of toxic reactions.
In pregnancy, the drug should not be prescribed during the first trimester and thereafter only to patients in whom the clinical situation warrants the potential risk. It should not be administered to nursing mothers.
Patients with increased intraocular pressure should be closely observed during treatment with this drug because of its anticholinergic effect.
Because of the drug's relationship to other tricyclic compounds, the possibility of activation of latent psychosis and, in the elderly, of confusion or agitation, should be considered.
Dizziness and drowsiness may occur and patients should be cautioned about the hazards of operating machinery or automobiles and of engaging in other hazardous tasks.
Use cautiously in patients with a history of coronary artery disease, organic heart disease, congestive failure or liver disease.
Before initiating therapy, the following laboratory procedures should be performed:
1. Complete blood and platelet counts which, if abnormal, should rule out the use of the drug.
2. Baseline evaluations of liver function.
During treatment with Tegretol, the following laboratory procedures should be performed:
1. Complete blood and platelet counts should be done at intervals of one week during the first month of drug treatment, every two weeks during the second and third months, and at monthly intervals thereafter for as long as the patient is taking the drug. A trend toward a decreasing white blood cell count should suggest a dosage reduction and more frequent laboratory and clinical evaluations. Should this trend continue, the drug should be discontinued.
2. Liver function tests must be performed at regular intervals during treatment with this drug since liver damage may occur during therapy. The drug should be discontinued immediately in cases of aggravated liver dysfunction or active liver disease.
3. Periodic eye examinations, including slit-lamp, funduscopy and tonometry, are recommended for patients being treated with this drug since many phenothiazines and related drugs have been shown to cause eye changes.
4. Complete urinalysis and BUN should be done on patients treated with Tegretol because of observed renal dysfunction.
Adverse Reactions Dizziness, drowsiness, unsteadiness on the feet, nausea, vomiting, aplastic anemia, transitory leukopenia, agranulocytosis, eosinophilia, leukocytosis, thrombocytopenia, purpura, abnormalities in liver function tests, cholestatic and hepatocellular jaundice, urinary frequency, acute urinary retention, oliguria with elevated blood pressure, albuminuria, glycosuria, elevated BUN, microscopic deposits in the urine, impotence, disturbances of coordination, confusion, headache, fatigue, blurred vision, transient diplopia and oculomotor disturbances, speech disturbances, abnormal involuntary movements, peripheral neuritis and paresthesias, depression with agitation, talkativeness, nystagmus, tinnitus, paralysis and other symptoms of cerebral arterial insufficiency, pruritic and erythematous rashes, urticaria, Stevens-Johnson syndrome, photosensitivity reactions, alterations in skin pigmentation, exfoliative dermatitis, alopecia, diaphoresis, recurrence of thrombophlebitis, erythema multiforme and nodosum, aggravation of disseminated lupus erythematosus, gastric distress, abdominal pain, diarrhea, constipation, anorexia, dryness of the mouth and pharynx, glossitis, stomatitis, fever, chills, adenopathy, lymphadenopathy, aching joints and muscles, leg cramps, conjunctivitis, left ventricular failure, aggravation of hypertension, hypotension, syncope and collapse, edema, aggravation of coronary artery disease and congestive heart failure. (Whether these cardiovascular effects are drug-related is not known. However, some of these complications have resulted in fatalities.) The necessity for discontinuing the drug should be dictated by the gravity and severity of the adverse reactions.
Dosage and Administration The drug should always be taken with meals, if possible.
Initial: One-half tablet (100 mg.) b.i.d. on the first day. Thereafter, the dose should be increased in one-half tablet (100 mg.) increments every 12 hours until freedom from pain is achieved. To relieve pain, between 200 mg. and 1200 mg. per 24 hours may be necessary.
Maintenance: Initial control of pain can be maintained in most patients with a dose of 400 mg. to 800 mg. daily. Maintenance doses may range between 200 mg. and 1200 mg. daily.
At least once every 3 months during treatment period attempts should be made to discontinue the drug or to reduce the dose to the minimum effective level.
Availability Round, white, single-scored tablets of 200 mg. in bottles of 100 and 1000. (B)46-820-A
For complete details, please see Prescribing Information.

retic activity throughout the day.
d one-a-day dosage, in the
g run, means few tablets to take
l few tablets to pay for.

Hygroton, brand of chlorthalidone, may mean troublesome side effects for certain patients. And you can't prescribe it in cases of demonstrated hypersensitivity to the drug or in severe renal or hepatic diseases.

Before writing it for your patients, please check the Prescribing Information. It's summarized on the next page.

lygroton

lorthalidone in edema and hypertension

Geigy

in edema and hypertension

A little Hygroton® can work a long day

chlorthalidone

Indications: Hypertension and many types of edema involving retention of salt and water.

Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.

Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue enteric-coated potassium supplements immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur.

Use with caution in pregnant patients. Since the drug may cross the placental barrier, adverse reactions which may occur in the adult (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential problems in the newborn.

Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents or other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. Barbiturates, narcotics or alcohol may potentiate hypotension. Because of the possibility of progression of renal damage, periodic determination of the BUN is indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated.

Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.

Take special care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.

Adverse Reactions: Nausea, gastric irritation, vomiting, anorexia, constipation and cramping, dizziness, weakness, restlessness, hyperglycemia, hyperuricemia, headache, muscle cramps, orthostatic hypotension, aplastic anemia, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin rashes, urticaria, purpura, necrotizing angiitis, acute gout, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Other reactions reported with this class of compounds include: jaundice, xanthopsia, paresthesia, and photosensitization.

Average Dosage: 50 or 100 mg. with breakfast daily or 100 mg. every other day.

Availability: White, single-scored tablets of 100 mg. and aqua tablets of 50 mg., in bottles of 100 and 1000.

Clinical Path Conference

Fulminant Meningococcemia

Case Report

THIS 22-YEAR-OLD white male draftsman was hospitalized for the acute onset of headache, vomiting, chills and muscle pain.

Past History

Thirteen years prior to this admission the patient had suffered an attack of poliomyelitis with transient paraparesis from which he had completely recovered. One year prior to this admission he had had an illness characterized by the rapid development of severe headache, vomiting, generalized muscle aching and fever. He was seen in the emergency room of Hennepin County General Hospital and was observed to have a temperature of 102 degrees and a questionably stiff neck. A lumbar puncture was performed and the cerebrospinal fluid was found to be normal and sterile on culture. His white blood count was 14,400 with 91 per cent neutrophils. Urinalysis was normal. He was discharged from the emergency room but was subsequently hospitalized elsewhere and treated for five days with penicillin. According to the patient, he was told that he had had "a bad case of flu." He made a full recovery.

Present History

Ten hours after the onset of his first symptoms he was admitted to the hospital, complaining of a severe frontal headache, some stiffness in his neck and leg muscles, chills and vomiting. Although he was a husky young man, he appeared acutely ill but was fully oriented. Temperature was 103 degrees; blood pressure 112/60; pulse 120.

Physical Findings

The eyes, including the optic fundi, were normal. Mild pharyngeal injection was observed but there was no exudate present. The ears and nose were normal. Slight to moderate stiffness of the neck was present. Examination of the heart and lungs was normal.

Some muscle guarding was observed in the abdomen, but there were no masses or organs palpable and the abdomen was non-tender. There were no palpable lymph nodes. The cranial nerves were normal. The knee and ankle tendon reflexes were unusually brisk but symmetrical. A Babinski sign was thought to be present on the left side. Frequent muscle contractions were noted in the legs. The skin was warm but no lesions were present.

Laboratory Studies

Hemoglobin on admission was 14.2 grams; white blood count 5,900 with 79% neutrophils and 21% lymphocytes. Platelet count was 150,000. The urine had a specific gravity of 1.022 with no albumin or sugar, and contained 40 to 60 red blood cells and 25 to 30 white blood cells per high power field. Serum sodium was 140, potassium 3.4, chloride 96 and CO_2 23 mEq/L. Total serum protein was 6.1 gm%, of which 3.7 gm% was albumin. Serum calcium was 8.9 mg%, alkaline phosphatase 17 King-Armstrong units, bilirubin 0.8 mg%, BUN 15 mg%, blood glucose 100 mg% , SGOT 23 units. The heterophile test was negative. The cerebrospinal fluid was clear and colorless; it contained two cells, both mononuclears. Its protein content

was 54 mg%, its sugar 78 mg%. An India ink preparation was negative, as was a stain for acid-fast bacilli. Gram stain of the cerebrospinal fluid was also negative. A chest roentgenogram was normal.

Progress

The patient was given aspirin and an injection of chlorpromazine. The following morning his temperature was 102.8 degrees. He was lethargic and slightly confused. He still had generalized muscle aching and pains in the joints of his hands and feet. A petechial rash was now observed over his entire body including the palms of the hands and the soles of the feet. A Gram-stained smear made from one of these lesions was negative. Vomiting recurred several times and his headache remained severe. Serum fibrinogen was measured and found to be 0.21 gm%. Seventeen hours after admission the rash was becoming increasingly blotchy and extensive and the patient's sensorium was more obtunded. At this point further diagnostic procedures were performed.

Clinical Discussion

Dr. Robert Gruninger:*

The protocol describes the patient to a certain point where further clinical tests were necessary to make a definitive diagnosis. I do not know what these tests were but hope to suggest what they might or should have been. Nor do I know the course of the subsequent events, but I hope to predict what that course could have been on the basis of the suggested laboratory tests. My objective is to arrive at a tentative diagnosis so that we might suggest further diagnostic tests.

First, I would like to review certain salient points and relate them to the disease process that affected this 22-year-old draftsman. He was admitted with an acute illness characterized by severe frontal headache, vomiting, fever and muscle pain. His past history is significant in that certain possibilities need to be considered. First of all, he had poliomyelitis as a child with apparently complete recovery. One year prior to admission, he had what was described as an attack similar to the present illness, characterized by fever, headache and neck stiffness. Spinal fluid at that time was negative. However, the white count was elevated. He was hospitalized elsewhere for five days with a diagnosis of flu-like syndrome. He presented here with headache, vomiting and muscle pain. There is considerable emphasis on the muscle pain in the protocol, but I am not sure how important this was. Significant physical findings revealed an elevated temperature, a tachycardia and some questionable neck stiffness. The knee and ankle jerks were brisk and there was a questionable Babinski. Muscle contractures were noted but not further defined. I would suggest that these represented fasciculations. However, there were no muscle findings to suggest tetany, spasm, or trismus. The fact that the skin was clear on admission is an important observation. Laboratory studies revealed that there was no anemia. The total white count is perhaps of interest in that there were 5,900 WBC with 79% neutrophils. Platelets were 150,000 which, I believe, we should consider on the low side. The findings in the urine disclosed significant numbers of red and white cells. The heterophile was negative and the BUN, SGOT, bilirubin and glucose were normal. Initially the spinal fluid was clear and only two monocytes were seen. Chest x-ray was normal.

I am sure that the clinician at this time, in spite of normal cerebrospinal fluid findings, thought that this patient might have an acute meningitis. He was initially treated with aspirin and chlorpromazine, but his temperature remained elevated. Two important events ensued. He developed petechiae over the entire body which progressed to confluent purpura and ecchymoses. Furthermore, he developed central nervous system changes evidenced by con-

*Assistant Professor, Department of Medicine, University of Minnesota Medical School.

fusion and lethargy. He still complained of severe headache and muscular pain. Thus further diagnostic tests were performed.

With this background, I would like next to consider what systems or general areas may be involved. His acute and fulminating course might possibly suggest a metabolic disease, possibly thyrotoxicosis, but there appears to be no supporting evidence. Could this be a cardiovascular disease? The purpura would be consistent with an endocarditis and septicemia; however, there is no history or findings suggestive of a cardiac lesion. I could not suggest pulmonary disease in the absence of a positive history and in the presence of a normal chest x-ray. In addition, renal disease might be considered; however, the urine findings were nonspecific and the presence of a normal BUN would seem to exclude a primary renal disease.

Central Nervous System

The events, however, do strongly suggest that he had primary involvement of the central nervous system. Meningitis was undoubtedly considered by the clinicians, though initially one could not say that he had a suppurative meningitis on the basis of the normal cerebrospinal fluid. There are some diagnostic tests that I would consider of additional importance; the first would be a repeat of the cerebrospinal fluid examination. His deep tendon reflexes were brisk but probably nonspecific; however, these could point to a central nervous system disorder. There was a questionable Babinski which probably was not of significance. Frequent muscle contractions were noted, and I would like to think that these were fasciculations. Some patients with polio may have fasciculations; possibly these could be some residual detected on the current admission. I would think that polymyositis and thyrotoxic or other myopathy could be excluded on the basis of the history and clinical findings. But with the progressive central nervous system symptoms I cannot exclude several processes, particularly a brain abscess.

Hematologic Process

Also I must consider a hematologic process, particularly with the progressive petechiae and purpura. This opens a whole new range of possibilities. For example, one might consider the nonthrombocytopenic purpuras which could include chronic renal disease, infections and allergic phenomena. Or this could be a thrombocytopenic purpura and, though I do not know what subsequent platelet counts showed, I would suggest that thrombocytopenia probably did occur. The various conditions giving rise to thrombocytopenic purpura raise a number of different possibilities. There are the essential or idiopathic variety and the symptomatic form which may be secondary to chemicals, toxins, medications, snake venom, x-rays, burns and other agents, none of which can be implicated in this particular case. There was no anemia or adenopathy to suggest or implicate another blood dyscrasia. Thrombotic thrombocytopenic purpura or Moschowitz syndrome is more frequently observed in women and is usually associated with a hemolytic anemia, not present in this particular case.

A variety of infections may cause this condition. Septicemia, either gram-negative or positive, subacute bacterial endocarditis, typhus, infectious mononucleosis, measles, and vaccinia have been implicated. Furthermore, fungus disease may induce low platelets; however, these are usually associated with diabetes, chemotherapy, or chronic lung disease. Collagen diseases raise a

whole new spectrum and cannot be entirely excluded; nevertheless, these were not suggested by the patient's history. Sarcoidosis and innumerable other conditions have also been implicated but do not appear to be factors in this case.

Intravascular Coagulating Syndrome

I would, however, like to invoke the intravascular coagulation syndrome. This syndrome remains a good possibility. There are a number of infectious diseases associated with it; in particular meningococcemia comes to mind. This certainly was suspected clinically as material was obtained from the skin lesion for microscopic examination; but this was negative for gram-negative diplococci. This fact, however, does not exclude such a diagnosis. Other bacteremias may result in a consumptive coagulopathy; *E. coli,* hemolytic Streptococcus, Staphylococcus, and Pseudomonas have been implicated. None of the aforementioned viral infections, however, seem to fit this case.

Meningococcemia

I would like to believe that this man had a septicemia, probably meningococcemia, and because of this developed the intravascular coagulation syndrome. Thus a number of additional diagnostic tests are indicated. A blood culture and repeat spinal fluid would be very helpful. In evaluation of the intravascular coagulation syndrome, a repeat platelet count and observation of clot formation are important. Furthermore, the clotting time and the prothrombin time should be considered; both would be prolonged. In addition, fibrinogen assay, partial thromboplastin and thromboplastin generation tests may be of additional value. There are at least three acceptable methods for fibrinogen determinations, and I would expect the values of these to be quite low in a consumptive coagulopathy. In addition, there are certain clotting factors, namely, factors V and VIII which should be considered; but of course these are generally not practical in an acutely ill patient with a fulminating course. In addition, fibrinolysis may be evident and could be evaluated with the euglobulin lysis test.

Some of these tests are not practical, as mentioned, and I would consider the four most important determinations in evaluation of consumptive coagulopathy to be the platelet count, the clotting time, the prothrombin time and the fibrinogen level. If these are abnormal, then a presumptive diagnosis of intravascular coagulation can be made, and I would then institute heparin therapy. The cause should then be determined. I must re-emphasize that a blood culture is indicated, but the results could take several days.

The one entity I cannot exclude is that of a brain abscess with septicemia. The initial symptoms one year before are quite consistent with the acute cerebritis associated with a brain abscess. These may present as a flu-like syndrome but then usually become quiescent; and it would seem unlikely that these would then present with an acute fulminating course in the absence of cerebrospinal fluid findings. I would like to think that this patient did have a flu-like syndrome a year ago rather than a cerebritis with secondary brain abscess. Certain diagnostic tests would be helpful in evaluating a brain abscess, namely, an electroencephalogram, and angiograms. Though I cannot exclude a brain abscess as a possibility, I believe that this patient had a fulminant meningococcemia, probably without meningitis, and secondary to this, the intravascular coagulation syndrome.

Comments

Dr. Robert Strom:*

Would you consider or exclude the Rickettsial diseases, particularly Rocky Mountain spotted fever, in this instance.

Dr. Gruninger:

I do not believe this patient had Rocky Mountain spotted fever for several reasons. We do not have a history of traveling in endemic areas, there is no documentation of a tick bite, and initially this lesion resembles a flea bite though ultimately it may become generalized and purpuric. Though this patient developed a rash while in the hospital, an initial tick bite is not described. Furthermore, Rocky Mountain spotted fever may be fulminating but is usually not as rapidly progressive as in this instance.

A Medical Student:

At what stage in this man's illness would you have instituted therapy.

Dr. Gruninger:

Initial laboratory findings of low platelets and low normal fibrinogen were suggestive of the intravascular coagulation syndrome. If additional coagulation studies, as already mentioned, were confirmatory, I would have instituted heparin therapy. Furthermore, with a presumptive diagnosis of meningococcemia and once a blood culture had been drawn, I would have begun penicillin treatment. This is now the drug of choice due to the increasing numbers of infections by group B organisms. Many are resistant to the sulfonamides.

Clinical Diagnoses

1. Fulminant meningococcemia
2. Intravascular coagulation syndrome

Pathology Discussion

Dr. Robert Anderson:*

Dr. Gruninger has presented a very complete analysis of the diagnostic problems presented by this patient and is entirely accurate in his interpretation of the events that transpired. This patient did succumb to a fulminant meningococcemia, and we are particularly interested in presenting this case not only because the histopathologic lesions are quite characteristic of those encountered in meningococcemia; but, furthermore, they are supportive of some of the more recent concepts in the pathogenesis of this entity.

Neisseria Meningitidis

The diagnosis was confirmed by cultures of both blood and cerebrospinal fluid which yielded Neisseria meningitidis. Furthermore, serotyping revealed the organism to be Group B. A further bit of confirmatory evidence was the presence of characteristic gram-negative diplococci within neutrophils present in smears of cerebrospinal fluid exudate obtained prior to death.

Meningococcemia

At necropsy his external appearance was quite typical for meningococcemia. There were numerous petechiae, ecchymoses and confluent purpura present

*Associate Pathologist, Department of Pathology, Hennepin County General Hospital.

over the trunk and extremities, with a predisposition for the latter areas. The head and neck were relatively spared. Furthermore, there were numerous petechiae and ecchymoses over serosal membranes, particularly prominent over both pleural surfaces, and to a lesser extent over the epicardium. Occasional petechiae were also present over peritoneal surfaces and the leptomeninges.

The brain was one of the tissues of prime interest. Upon removal of the calvarium, there was an obvious diffuse milkiness of meninges over the convexities. This exudate was concentrated in sulci resulting in accentuation of cortical vessels. There was a moderately heavy purulent exudate at the base of the brain, extending over the inferior temporal lobes and the inferior surface of the cerebellum. On sectioning, the white and grey matter were spared; however, there was an exudative thickening of the meninges. Histologic examination showed an acute purulent meningitis characterized by extensive neutrophilic infiltrate of leptomeninges (Figure 1). The white matter was uninvolved and the cortex showed only occasional leucocytic margination of small cortical vessels.

Terminal failure was undoubtedly reflected in the marked bilateral hydrothorax and pulmonary edema. Both pleural cavities contained approximately one liter of blood-tinged fluid. The lungs were massively edematous and together weighed 2700 grams. Sections disclosed widespread edema and marked congestion, but no sites of pneumonitis.

The adrenal glands were perfectly normal. There was no evidence of hemorrhage, necrosis or cortical lipid depletion. Microscopically, the only change of note was the presence of a pseudotubular degeneration, a nonspecific finding not infrequently present in overwhelming infectious states. The abdominal viscera were congested but otherwise normal, and the kidneys were not remarkable.

The heart was the site of a fairly striking myocarditis. Although this has been observed with some frequency in meningococcemia, the pathogenesis

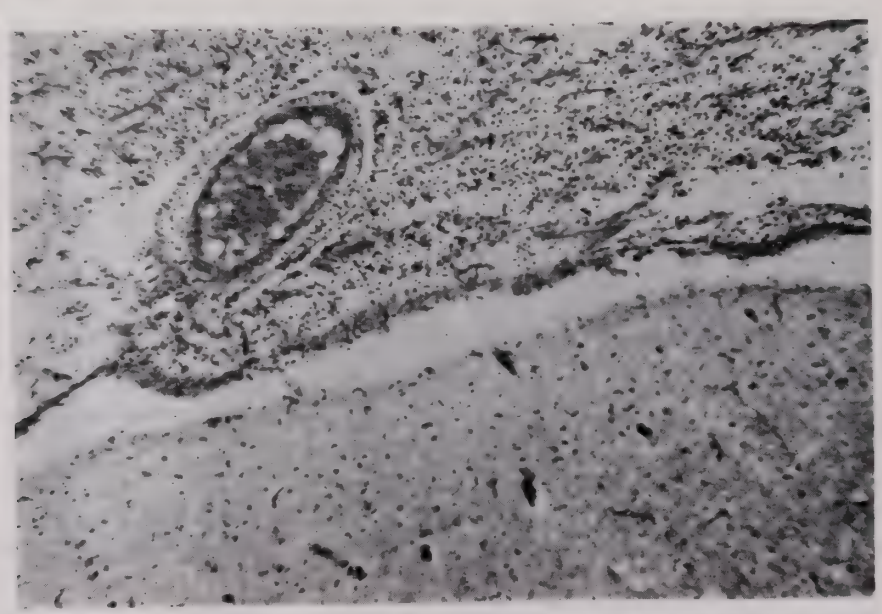

Fig. 1—A representative section from the cerebral convexities discloses extensive acute purulent meningitis.
Hematoxylin and eosin. ×100

and histopathology of these lesions have received little attention. Generally, the infiltrate was present in two areas: predominantly perivascular in location and to a lesser extent in and around myofibers. The perivascular infiltrates were polymorphous in nature and comprised principally of polymorphs together with increased numbers of Anitschkow myocytes, the counterpart of the reticulum cell in the heart (Figure 2). This latter change might suggest some injury or stimulation of the reticuloendothelial system. Furthermore, vessels in the area of the inflammation showed increased prominence and swelling of endothelial cells, perhaps indicative of endotoxin-induced

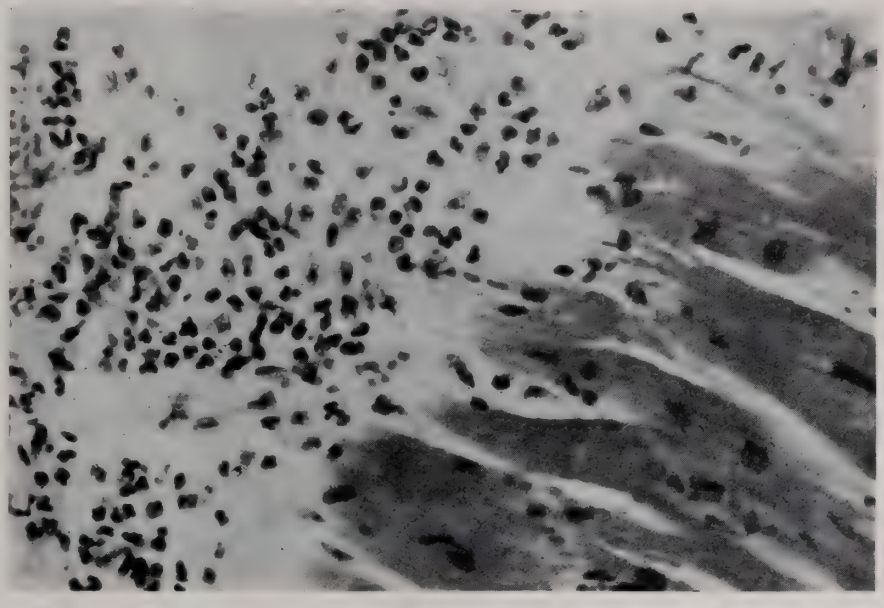

Fig. 2—Acute interstitial myocarditis in which a fairly extensive neutrophilic infiltration is interspersed with a few monocytes and Anitschkow myocytes.
Hematoxylin and eosin. ×200

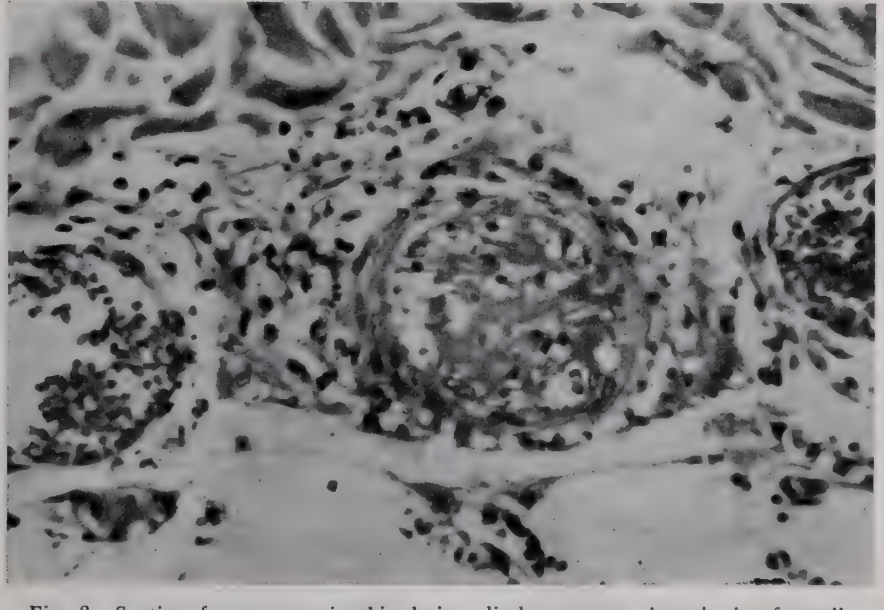

Fig. 3—Section from purpuric skin lesion discloses acute thrombosis of small dermal arteriole associated with an acute vasculitis.
Hematoxylin and eosin. ×200

injury. Myofibers for the most part were well preserved, though some did show necrobiotic changes characterized by either nuclear pyknosis or occasional foci of cytomyolysis, a change possibly secondary to endotoxin-induced injury.

Vascular changes in small vessels of the skin were of considerable interest and illustrative of those stages of vascular damage that have been described in meningococcemia. The earlier changes are characterized by endothelial swelling, fragmentation, desquamation of endothelial cells and sludging of red cells. Meningococci have been identified within endothelial cells in this stage, though they were not evident in this instance. The latter stages of injury are characterized by polymorphs infiltrating damaged endothelium, the vessel wall, and the perivascular tissues. An acute vasculitis as well as necrosis of vessel wall may occur. Of particular note is the development of platelet and fibrin thrombi at this stage, which may become quite widespread and which was readily evident in this patient (Figure 3).

These stages of vascular damage were well documented in a study approximately 20 years ago by Drs. Hill and Kinney. It was their concept that the initiating insult was the localization of meningococci within the endothelial cells with subsequent inflammation and vascular damage. However, it has been observed in subsequent studies that meningococci are infrequently found in endothelial cells, as was true in this case. Many authorities now believe that these changes within small vessels of the skin and subcutaneous tissues represent multiple local Shwartzman reactions in which skin sites become prepared by endotoxin in the early bacteremia phase, with the provocative phase occurring later from the continuing bacteremia. Similar changes with extensive sinusoidal thrombosis are often present in the adrenal glands. This endocrine is now also considered to be a site for the Shwartzman reaction, and some investigators suggest that this phenomenon is the precursor of adrenal hemorrhage and necrosis characteristic of the Waterhouse-Friderichsen syndrome. Glomerular capillary thrombi are also fairly common in meningococcemia, though they were not evident in this case. A few cases of renal cortical necrosis have recently been described in meningococcemia, and this would seemingly implicate a generalized Shwartzman reaction as an additive factor in the pathogenesis of meningococcemia in some instances.

Consumptive Coagulopathy

The extensive vascular changes with thrombosis also implicate a different process worthy of comment. Hill and Kinney in their study emphasized the purpuric nature of meningococcemia and considered it to be directly related to the widespread vessel thrombosis with depletion of circulating platelets. They described the syndrome of consumptive coagulopathy though they did not coin this term. The frequent occurrence of this syndrome in patients with meningococcemia has been clearly established, and it is thought to be initiated by the Shwartzman reaction. The patient under consideration today did suggest an early consumptive coagulopathy evident by hemorrhagic tendency, diminished platelets, and prolonged prothrombin time. Small-vessel thrombosis can be quite widespread and is usually evident in vessels of the skin and subcutaneous tissue, the kidneys, adrenals, pancreas and lungs to a lesser extent. One site frequently overlooked is the choroid plexus. I have had the opportunity to study several cases of meningococcemia, and in all of these, including this present case, the choroid plexus was the site of numerous small vascular thrombi. In conclusion, this young male succumbed to ful-

minant meningococcemia. The histopathologic lesions were quite characteristic of those seen and are supportive of the concept that an interaction of endotoxinemia, multiple Shwartzman reactions, and consumptive coagulopathy is of prime importance in the pathogenesis of this entity.

Pathological Diagnoses

1. Fulminant meningococcemia with acute purulent meningitis
2. Intravascular coagulation syndrome

Erratum

The June* issue of MINNESOTA MEDICINE contained a short biography of Joseph N. Gehlen, M.D., in recognition of his 50 years of distinguished service in the practice of medicine. The Board of Editors wishes to correct this biography as follows:

> JOSEPH N. GEHLEN, M.D., St. Paul, Minnesota . . . specialized in internal medicine and obtained his medical education at Creighton University at Omaha, Nebraska; he was graduated in 1918. Earlier, he had received his B.S. degree from St. Martins College in Olympia, Washington. He interned at Lord Lister Hospital in Omaha, the U.S. Naval Hospital in Newport, Rhode Island and St. Mary's Hospital in Providence, Rhode Island. He practiced from 1919 to 1920 in LeMars, Iowa, his native community. After coming to Minnesota, he did post-graduate work at the University of Minnesota and became epidemiologist for the Minnesota State Board of Health. He began practice in St. Paul in 1925 and has served on the staffs of Ancker, Miller, St. Joseph's and St. Luke's Hospitals. He was chief of the tuberculosis service at Ancker Hospital from 1939 to 1958. He is a member of the American College of Chest Surgeons, the American Society of Internal Medicine and the Trudeau Society.

Review—

The Metabolic Effects of the Periwinkle Alkaloid Vinblastine

VINBLASTINE IS an extract of the plant *Vinca rosea Linn* (periwinkle). It was first isolated as the sulfate salt by Noble, Beer, and Cutts[15] at the University of Western Ontario. The characterization was carried out by Neuss et al.[11,12,13] at the Lilly Laboratories. This latter group found it to be a complex molecule, containing both an indole and indoline moiety. The indole portion is related to catharanthine, whereas the indoline portion is related to vindoline. Thus, in essence, it is a non-symmetrical dimeric alkaloid (Figure 1). Clinically vinblastine finds use in the treatment of Hodgkin's disease and also in the treatment of choriocarcinoma.

Physical Values

Vinblastine is a dimeric alkaloid which contains both an indole and indoline moiety. It has two pk^a values, 5.4 and 7.4 (in H_2O). Maximum ultraviolet absorptions are at 214 and 259 mu. It is dextrorotatory with $(\alpha)^{26}$ $CHCl_3$ equal to +72, and has a melting point (decomposition) of 211-216°C.[8]

Structure and Activity

Vinblastine no longer produces its biologic effect if the structure of the vinblastine molecule is altered in relatively minor ways[14] (Figure 2).

The Dimer VLB and Its Parent Monomers

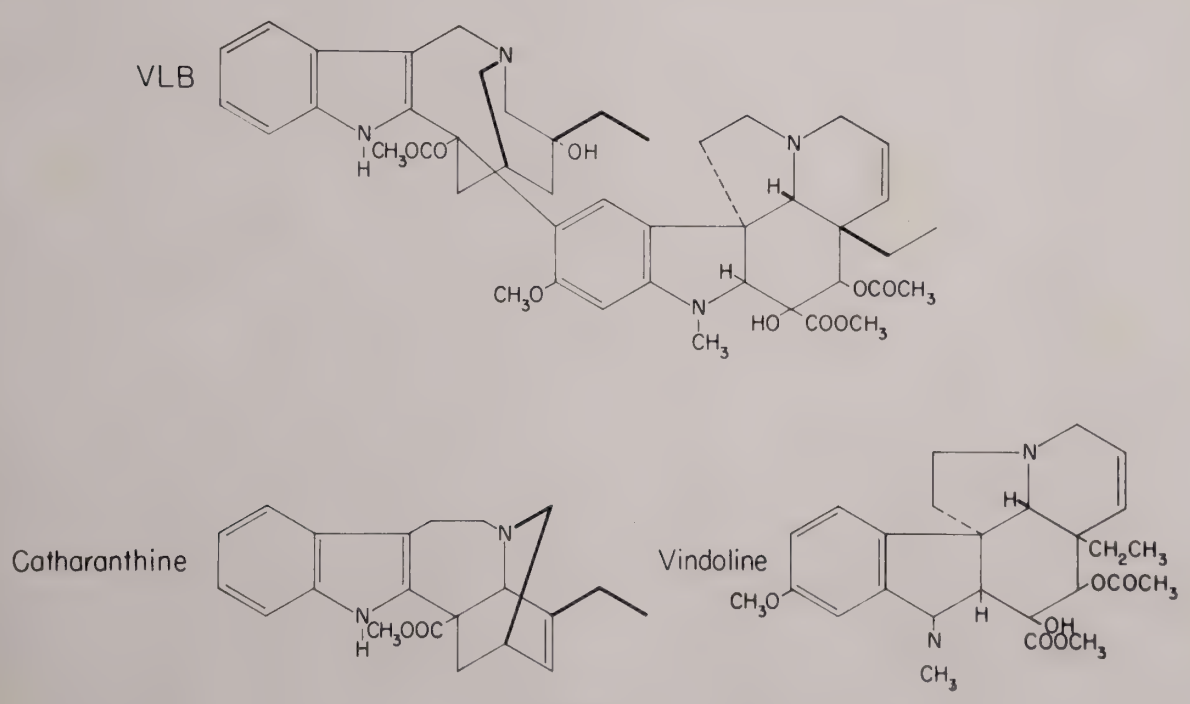

Figure 1

That such small structural changes are important in determining anti-tumor effect can be seen from the fact that few other alkaloids derived from the periwinkle plant are active anti-tumor agents. Those that are, e.g., vincristine, differ quantitatively and qualitatively in their effects.

It is no easy matter to account for differences in biologic action with slight molecular changes but there are a number of explanations that come to mind:

1. A reactive site may be altered by chemical combination, as in amidization or quaternization of the indole nitrogen of vinblastine.
2. Addition of groups may result in steric hindrance of reactions, as in the acetylation of the hydroxyl groups of vinblastine, particularly if vinblastine, or a metabolic product of vinblastine, interferes with an enzyme system.
3. Changes in charge distribution may affect the reactivity of vinblastine, as in the hydrogenation of double bonds.

All of the above explanations hold for enzymic and non-enzymic mechanisms, in the former case because of direct changes in reactivity, in the latter case because of structural changes as well.

Finally, it should be remembered that a structural change may hinder the metabolism of a compound more or less severely, or it may make for a different product of metabolism, which may or may not be active.

Metabolism of Vinblastine

In studies conducted by Beer et al.[1] in which vinblastine was labeled with tritium by the Wilzbach irradiation method, it was found that some 5% of dose radioactivity was excreted in the urine over a 26-hour period following injection of the drug into rats. Two per cent of this amount appeared in the urine within the first three hours. After the same 26-hour time interval, 1 ml. of blood contained 0.08 ± 0.01% of the injected radioactivity, or approximately 1.2 ± 0.15% of the dose in terms of total blood volume. In an additional study, Beer et al.[2] reported results in agreement with the above. This second study included dose-radioactivity for a number of organs (Table). It is interesting to note that some 25% of dose-radioactivity from labeled vinblastine is excreted via the gut, and together with the excretion in the urine, nearly one third of the dose leaves the rat by these routes. Of the remaining two thirds, only 2.0% is left unchanged by the liver.

It remains to be seen whether the activity of the liver enhances or decreases the effect of vinblastine. It is known, however, that the intraperitoneal dose for the LD50 in mice is much less than the intravenous dose (3.2 mg/kg vs. 17.5 mg/kg) and that the oral dose is

TABLE[a] 1.

[e]0-24 hr urine; collected as one sample.

higher than either (33.1 mg/kg).* This would indicate two things: (1) the liver probably modifies the drug, and (2) stomach acidity inactivates the drug, or prevents absorption.

In an experiment carried out by the author,† no change in the ultraviolet spectrogram of vinblastine appeared after incubating the drug at 37°C and pH 7.4 for six hours in an attempt to simulate body environment in terms of physical parameters. Four mg of vinblastine was dissolved in 50 ml. of phosphate buffer in a glass test tube. The tube was placed in a 37°C water bath and mechanically shaken throughout the six hours of the experiment time. The ultraviolet spectrogram was done on the buffer solution.

The absence of change in the spectrogram indicates that body pH and temperature *per se* do not alter drug configuration so far as ultraviolet analysis can show.

Vinblastine and Cell Respiration‡

In studies carried out by Katchman et al.,[19] the metabolism of human cancer cells as modified by drug action was measured in terms of three parameters:

1. Oxygen uptake as a measure of respiratory activity,
2. Formation of lactic acid as a measure of aerobic fermentation, and
3. Glucose disappearance or utilization as a measure of total carbohydrate metabolic potential. Only the effect of vinblastine will be reported here.

*Data from Eli Lilly Company.
†Unpublished data.
‡Experimental data in this section from Katchman et al; See original paper for discussion of technique and drugs used.

Structural Modifications of VLB which are Biologically Inactive

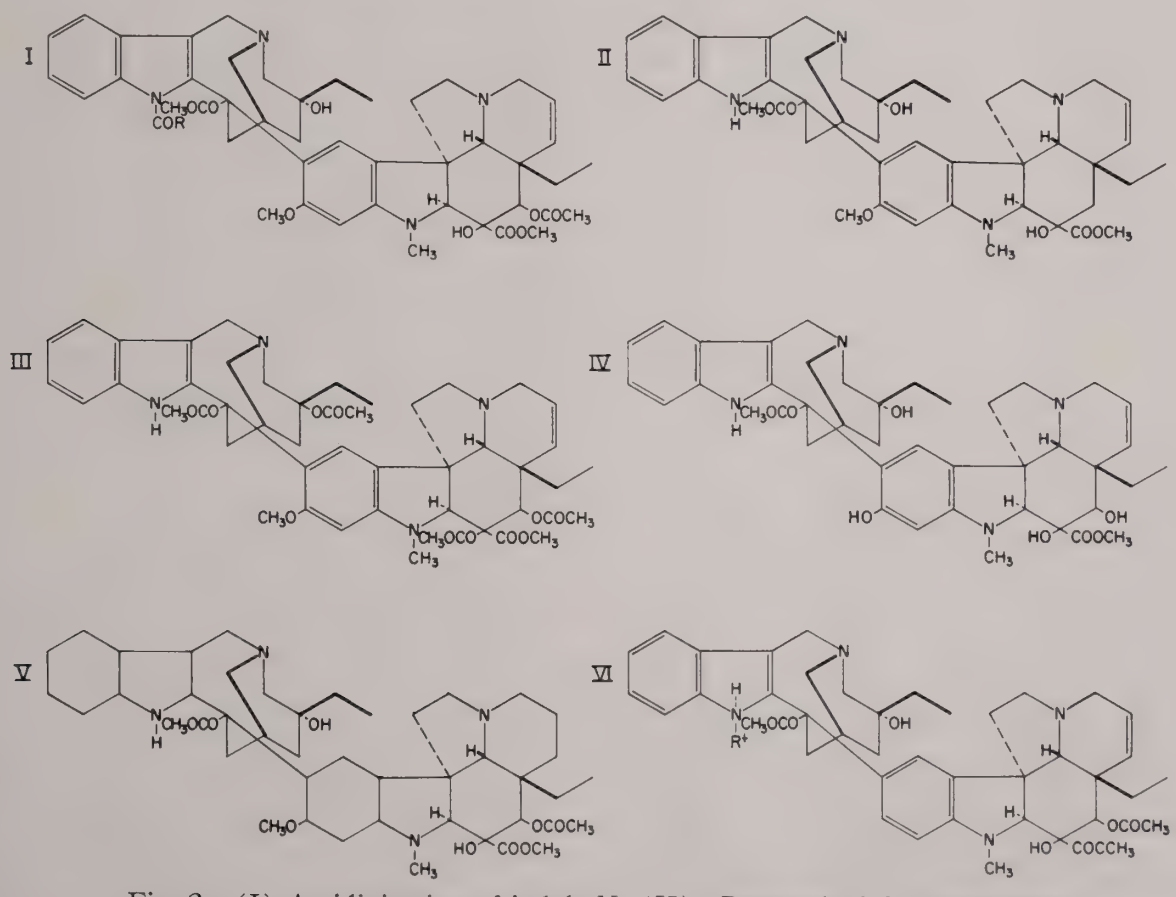

Fig. 2—(I) Amidinization of indole N. (II). Removal of C_4 acetyl group of vindoline moiety. (III) Acetylation of hydroxyls. (IV) Reduction with $LiAlH_4$. (V) Hydrogenation of double bonds. (VI) Quaternization of indole N.

Oxygen Uptake

When vinblastine is added to a suspension of human cancer cells (leukemia), the effect of the drug is to decrease oxygen uptake. This effect of vinblastine on cell respiration as measured by oxygen uptake is greater than for other common anti-cancer drugs. This correlates with the severity of leucocytopenia produced by the drug. Vinblastine reduces oxygen uptake from 49 ml/hr. to 34 ml/hr. over a 90-minute test period and at a dose of 3.3 mcg/10^6 cells. This represents a 30% reduction in uptake of O_2 (Figure 2).

Lactic Acid

Cancer cells produce lactic acid even while in the presence of O_2.* When vinblastine is added to a suspension of cancer cells, lactic acid production is increased above normal values from 0.44 mg. to 1.00 mg. over a period of 190 minutes and with a concentration of vinblastine of 3.6 mcg/10^6 cells. Again, the effect of vinblastine is greater than for other chemicals studied.

*These cells also exhibit the Crabtree effect. When glucose is added to these cells, O_2 uptake decreases.

Glucose

Glucose utilization by cancer cells in the presence of vinblastine (3.3 mcg/10^6 cells) increases from the control value of 0.2 mg. to 0.6 mg. Essentially all glucose can be accounted for as glucose equivalents used in respiration and lactic acid production. This fact, coupled with the observation that at sufficiently low concentrations vinblastine does not inhibit respiration, makes the agent a true Pasteur effect inhibitor; i.e., it stimulates lactic acid production without inhibition of respiration (Figure 3).

Vinblastine and Nucleic Acid Metabolism

Richards and Beer[16] studied the effect of vinblastine on nucleic acid synthesis using 14C-Formate. The following results were obtained:

1. Nucleic acid synthesis was depressed.
2. Desoxyribonucleic acid synthesis was depressed more than ribonucleic acid synthesis.
3. Desoxyribonucleic acid-adenine and desoxyribonucleic acid-guanine were decreased below control levels to a greater extent than desoxyribonucleic acid-thymine.

Richards and Beer suggest two possible mechanisms for the inhibition of nucleic acid synthesis. Either there is interference with the polymerase reaction, or there is decreased synthesis of nucleotide precursors. They consider the latter possibility more likely in view of the differential effect on adenine and guanine vs. thymine synthesis. Also there is evidence that there is no interruption in synthesis of inosinic acid or of thymidylic acid.

Vinblastine and Mitosis

Vinblastine is a potent metaphase arrestor showing dosage effects comparable to those of colchicine and sometimes surpassing them. While the Syrian hamster proves resistant to colchicine, vinblastine produces complete metaphase arrest of Syrian hamster cells.[3] Unlike colchicine, the arrest is reversible by treatment with various amino acids, particularly glutamic acid. Although this is one of vinblastine's most striking properties, the stathmokinetic effect does not correlate well with antitumor activity of the drug.[7,17]

The appearance of the chromosomes of cells arrested in metaphase by vinblastine is that of the colchicine-mitosis pattern, where chromosomes are clumped, shortened, and paired. The nuclei are pyknotic and take the form of the ball mitosis. Occasionally exploded metaphases are seen.[3,4,5,17]

Vinblastine and Amino Acids

Johnson et al.,[7] by adding various amino acids to vinblastine treated systems, found that the effect of vinblastine was considerably reduced.[7] This effect was seen at low doses of vinblastine. With higher doses, amino acids had no effect. The compound found to be most effective in this respect is L-glutamic acid.

Vinblastine and Prophage-Inducing Action

Endo et al.[6] have reported that certain chemotherapeutic agents have prophage-inducing ability that correlates well with tumoricidal action of the agents. Endo and colleagues observed induction of lysogenic bacteria with mitomycin C and various of its N-substituted derivatives where the substituting group is an alcohol. Vinblastine failed to show any such action.

Discussion

The metabolic effects of vinblastine suggest possible correlations between its effects on respiration and its effects on nucleic acid synthesis. Vinblastine has an effect both on the oxygen uptake of cells and on their production of lactic acid. It affects the utilization of glucose as well. In addition, it apparently reduces the synthesis of nucleic acids, probably by interfering with the formation of nucleotides.

A possible explanation for the increased lactic acid production and increased utilization of glucose is suggested by the fact that vinblastine interferes with nucleotide formation; that is, the inhibition of nucleotide synthesis causes a shortage of the cells' energy-storing compounds, particularly adenosine diphosphate. Consequently the cells revert to glycolytic respiration, the metabolism of glucose goes up, and the output of lactic acid rises. Along with these changes, oxygen use falls.

Simply then, the observation that more glucose is metabolized, more lactic acid is produced, and less oxygen is used up constitutes evidence that the cells have reverted to aerobic fermentation with the less efficient energy production per glucose molecule. Such reversion ordinarily occurs in anoxia of tissues and is seen in shock as it progresses to irreversibility. The cells however were not anoxic in the experiments of Katchman et al.,[19] which leads one to suppose that the trichloroacetic acid cycle is partially inoperative for reasons other than oxygen lack.

The fact that cancer cells normally produce lactic acid in the presence of oxygen would seem to suggest that their energy manufacturing mechanisms are already suffering from malfunction. Alternatively, the mechanism is working at full capacity, so that adenosine diphosphate becomes scarce, and additional energy is supplied glycolytically.* In consequence, any agent which selectively attacks the energy-forming mechanisms produces a favorable anti-tumor response over and above damage to normal cells. This then could explain the greater susceptibility of certain cancer cells to vinblastine.

It has already been stated (v.s.) that there is no straight-forward correlation between the stathmokinetic and the anti-tumor effects of vinblastine. Thus it would seem that anti-tumor action is achieved primarily by making an already inefficient mode of energy production even more so to the point of causing cell death by a mechanism other than simple mitotic arrest and interphase "death." Tumor cells by this hypothesis are "energy-starved" in relation to other cells. Tumors that are less metabolically active are likely to respond more like normal cells to vinblastine.

This may not be the only reason vinblastine has a pronounced action on some cells and not on others. Quite possibly some of the differential action can be explained enzymatically. It is possible that enzymes differ according to stem cell type and that while reticuloendothelial cells are affected, nerve cells are not, because a particular enzyme or enzymes, due to structural characteristics, can be affected by vinblastine in the first case and not in the

*The cells are metabolizing so rapidly that they utilize the faster energy-forming glycolytic sequence to maintain their rate. The Crabtree effect would support this idea.

second*.

If the effect is one of enzyme competition, it is likely to involve nucleotide precursors after and including inosinic acid (Richards and Beer). It is possibly competitive because the drug has an increasing effect with increasing dose.

As for the effects of glutamic acid, these can be explained by postulating that vinblastine is a competitor of inosinic acid, or a competitor of a product of inosinic acid leading to the nucleotides. By increasing glutamic acid, the amount of synthesized inosinic acid increases, and in effect, the acid becomes more competitive.

The Warburg Shift

Four decades ago, the biochemist Warburg postulated that respiratory injury is the cause of cancer, and pointed to the shift to aerobic fermentation exhibited by cancer cells.[18] It is apparent from the work of Katchman and his co-workers that vinblastine, and to a lesser extent other antitumor drugs, can be considered Warburg-shift agents. But what is most important, the action of vinblastine and these other drugs indicates that interference with nucleic acid chemistry is associated with the Warburg shift.

Conclusion

The anti-tumor effect of vinblastine may possibly be due to its effect on cell energy mechanisms. Adenosine diphosphate production is decreased by retarded nucleotide production. Its mitotic effects may also relate to retarded nucleotide production as may its action as a Warburg-shift producer. Its selective nature of action is possibly due to a number of factors (energy differences, enzyme differences, permeability differences). Finally, its therapeutic ratio may depend on the greater energy needs of cancer cells along with their decreased efficiency in generating energy because of their reliance on the glycolytic pathway. There may be dependence on glycolysis because of some inherent malfunction, or because of simple adenosine diphosphate shortage.

It's the Law

Government Liable for Killing by Mental Patient on Leave

Damages of $200,000 were awarded against the government under the Federal Tort Claims Act for the death of a woman, who was killed by her husband, a mental patient on leave of absence from a VA hospital. The evidence established that the hospital personnel were negligent in their evaluation of the patient's condition, and in the procedure followed, when he was placed on leave of absence, a Federal Court in North Dakota ruled. The psychiatrist in charge of the case gave the patient involved a one-week leave of absence to attend a funeral.

Abbott Antihypertensive Building Blocks

A simplified approach to the practical management of hypertension

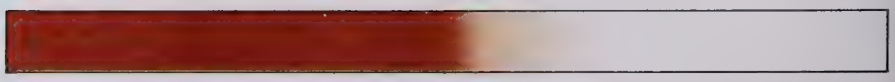
Enduron: (methyclothiazide) A basic building block for mild hypertensives

Excellent day-long Na^+ output, yet easy on the K^+

Enduron provides an excellent starting therapy. Your patient's sodium excretion is greatly enhanced. Yet potassium loss is low.

The therapeutic action is smooth, and persists for a full 24 hours. With Enduron you can prescribe convenient once-a-day dosage without skimping your patients on day-long thiazide effectiveness.

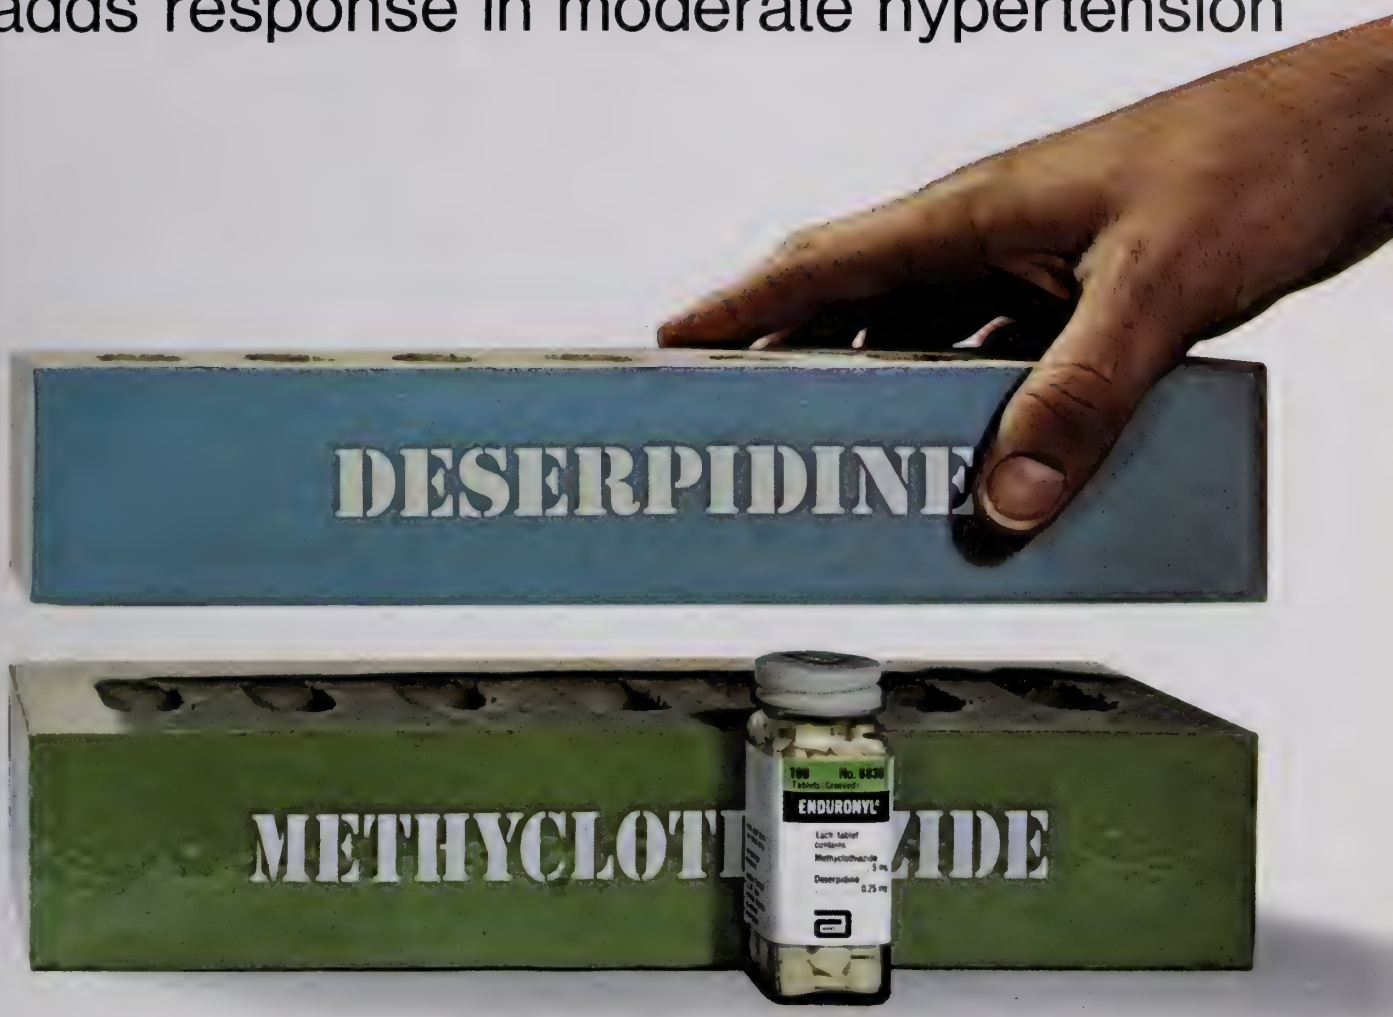
Of course, as with all thiazides, supplemental dietary potassium should also be considered.



Use Enduron as a basic therapy in patients with mild to moderate hypertension. A single 5-mg. tablet each day is ample in most cases.

Once a day, every day

ENDURON®



METHYCLOTHIAZIDE

MILD TO MODERATE TO SEVERE

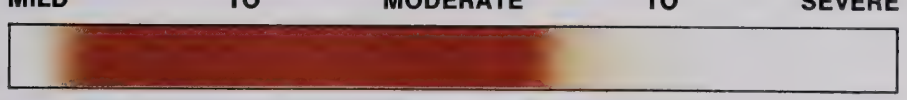
See Brief Summary on final page of advertisement

Enduronyl: Its deserpidine component adds response in moderate hypertension

Less frequent rauwolfia side effects than with reserpine

When you wish to build further response, consider shifting to Enduronyl.

Enduronyl adds a building block of *deserpidine*. This is a purified rauwolfia alkaloid available only from Abbott. It adds good antihypertensive and tranquilizing activity. Yet its incidence of untoward effects, particularly lethargy and depression, is lower than with reserpine.

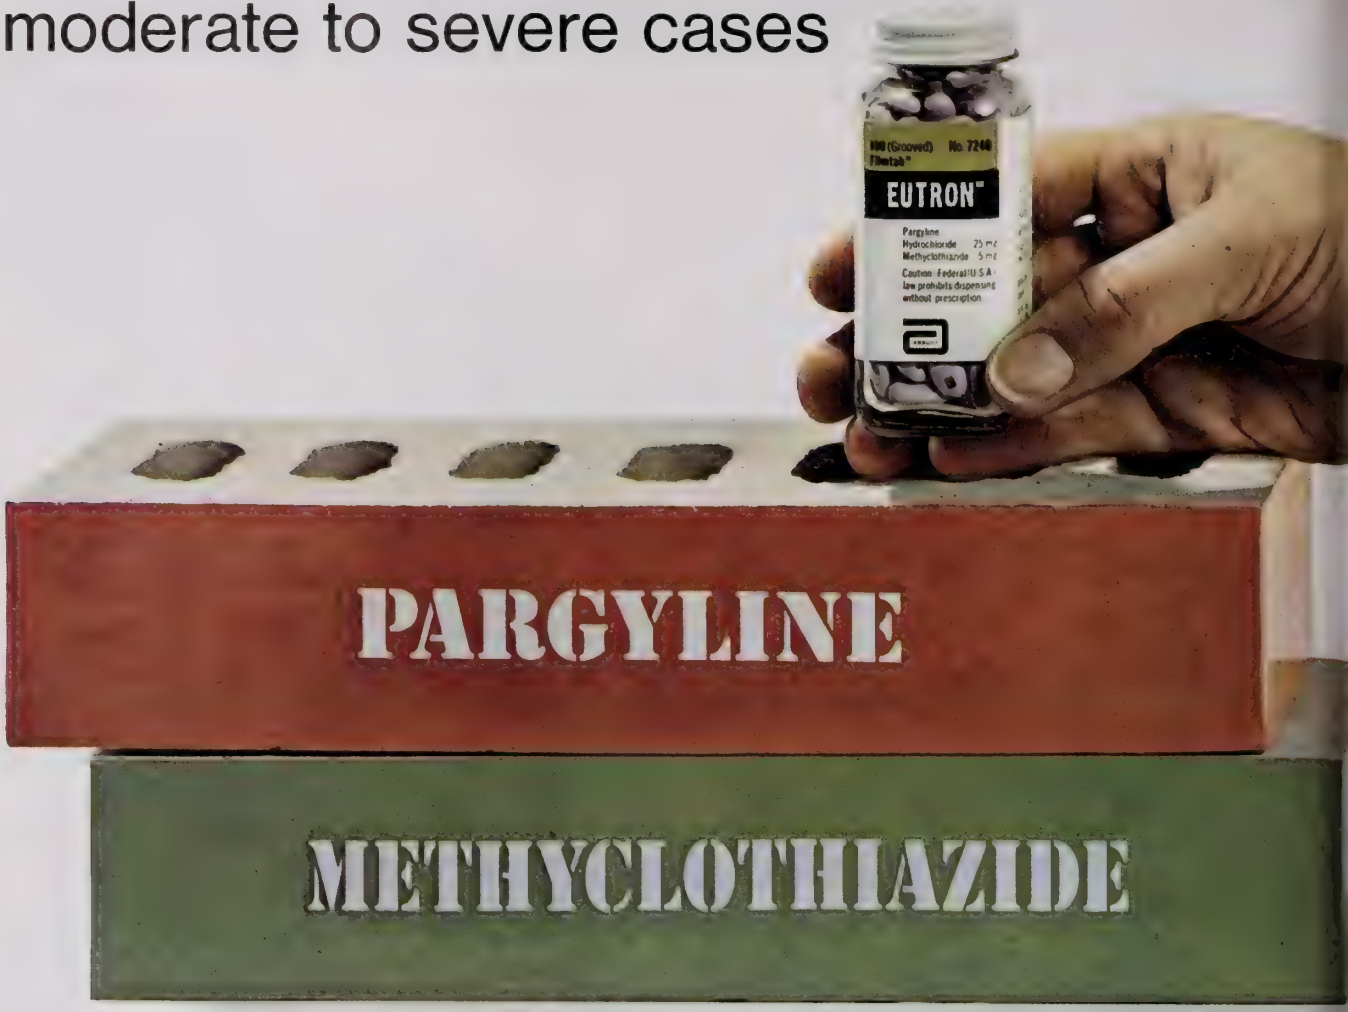


Enduronyl is available plain or Forte. The latter provides its variation where most helpful, by doubling the deserpidine.

Use Enduronyl for patients throughout the broad range of mild to moderately severe hypertension.

Once a day, every day

ENDURONYL®



METHYCLOTHIAZIDE 5 mg. with DESERPIDINE 0.25 mg. or (FORTE) 0.5 mg.

See Brief Summary on final page of advertisement

801094

Eutron: A unique combination for handling moderate to severe cases

Affords almost uniform diastolic reduction in all body positions

Eutron lowers diastolic pressures nearly equally, whether your patient is standing up or lying down.

Thus, in clinical trials, average *standing* diastolic readings were reduced from 112 pre-treatment to 90 post-treatment; *sitting* from 115 to 95; and *recumbent* from 112 to 94.

Note that following Eutron, the diastolic reductions were nearly alike in all three body positions.

Use Eutron for managing your moderate to severe cases. Its building blocks enhance each other; hence lesser doses often suffice.

Once a day, every day

EUTRON™

PARGYLINE HYDROCHLORIDE 25 mg.
with METHYCLOTHIAZIDE 5 mg.

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

ENDURON® | ENDURONYL®

METHYCLOTHIAZIDE

Each tablet contains Methyclothiazide 5 mg. with Deserpidine 0.25 mg. or 0.5 mg.

Indications: Edema and mild to moderate hypertension (Enduron), and mild to moderately severe hypertension (Enduronyl). More potent agents, if added, can be given at reduced dosage.

Contraindications: Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease or impending hepatic coma (hepatic coma due to hypokalemia has been reported in patients on thiazides). Do not use Enduronyl in severe mental depression, suicidal tendencies, active peptic ulcer, or ulcerative colitis.

Warnings: Consider possible sensitivity where there is history of allergy or asthma. If added potassium is indicated, dietary supplementation is recommended. Reserve enteric-coated potassium tablets for cautious use only when necessary, as they may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation often requiring surgery; discontinue them immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occurs. Neither Enduron nor Enduronyl contains added potassium.

Precautions: Use thiazides cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery, thiazides may reduce response to vasopressors, and increase response to tubocurarine. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia) in all patients. In hypokalemia (especially in digitalized patients) give supplemental potassium. In hypochloremic alkalosis, give supplemental chloride.

Use rauwolfias with caution in patients with history of peptic ulcer. Rauwolfias with anesthetics may produce hypotension and bradycardia. Discontinue Enduronyl two weeks before elective surgery. Consider vagal blocking agents during emergency surgery. In epilepsy, adjust anticonvulsant dosage. In electroshock, shorten stimulus strength and duration. In occasional patients with depressive tendencies, rauwolfias may precipitate severe mental depression that usually disappears when drug is stopped.

Adverse Reactions: Thiazide reaction include blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, serum uric acid or blood sugar; anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, symtomatic gout, and pancreatitis. Cutaneous vasculitis in the elderly has been reported with other thiazides. Adverse effects with deserpidine are qualitatively similar to those with reserpine, but their incidence is lower. These include nasal stuffiness, abdominal cramps or diarrhea, nausea, headache, weight gain, reduced libido and potency, peptic ulcer aggravation, epistaxis, skin eruption, asthma in susceptible patients, electrolyte imbalance, excessive salivation, and a reversible Parkinson's syndrome. Excessive drowsiness, fatigue, weakness, and nightmares may signal mental depression. Thrombocytopenia, purpura, and a symptom manifested by dull sensorium, deafness, uveitis, glaucoma, and optic atrophy are rare allergic reactions to other rauwolfias. Hypotension from antihypertensive agents may precipitate angina attacks in susceptible individuals. Usually adverse reactions disappear when drug is withdrawn.

EUTRON™

Each tablet contains Pargyline Hydrochloride 25 mg. with Methyclothiazide 5 mg.

Indications—Moderate to severe hypertension.

Contraindications—Pheochromocytoma, paranoid schizophrenia, hyperthyroidism and advanced renal failure. Not recommended in malignant hypertension, children under 12, pregnant patients.

Do not use with: centrally or peripherally acting sympathomimetic drugs; foods high in tyramine (e.g., aged and natural cheeses); parenteral reserpine or guanethidine; imipramine, amitriptyline, desipramine, nortriptyline or their analogues; other monoamine oxidase inhibitors; methyldopa or dopamine; separate Eutron and these agents by two weeks.

Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease; impending hepatic coma from thiazide-induced hypokalemia.

Warnings—Patients: 1. No other drugs (particularly "cold preparations" and antihistamines), cheese or alcohol without physician's consent. 2. Promptly report orthostatic symptoms, severe headache, other unusual symptoms. 3. Angina pectoris or coronary artery disease patients must not increase physical activity with improved anginal symptoms or well-being.

Physicians: 1. Use antihistamines, hypnotics, sedatives, tranquilizers and narcotics (meperidine contraindicated) cautiously in reduced doses. 2. Stop Eutron two or more weeks before elective surgery; in emergency surgery reduce premedication (narcotics, sedatives, analgesics, etc.) to 1/4 to 1/5; carefully adjust anesthetic dosage to patient response. 3. Use cautiously in advanced renal failure. 4. Pargyline may induce hypoglycemia. 5. Consider possible sensitivity reactions when a history of allergy or asthma is present. 6. If potassium is indicated, dietary supplement is recommended; enteric-coated potassium tablets may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation frequently requiring surgery; discontinue medication immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occurs; Eutron does not contain added potassium. 7. Possible systemic lupus erythematosus has been reported for thiazides.

Precautions—Pargyline: Use cautiously at reduced dosage: caffeine, alcohol, antihistamines, barbiturates, chloral hydrate, other hypnotics, sedatives, tranquilizers, narcotics. Periodically do urinalyses, blood counts, liver function tests, etc. Use with caution in liver disease. Watch for orthostatic hypotension, especially in impaired circulation (e.g., angina pectoris, coronary artery disease, cerebral arteriosclerosis); also, augmented hypotension in concomitant febrile illnesses. Reduce or discontinue if hypotension is severe. In impaired renal function watch for cumulative drug effects, elevated BUN and other evidence of progressive renal failure; withdraw drug if these persist. In surgery increased central depressant response (hypotension and increased sedative effect) can be controlled by (1) discontinuing at least two weeks prior; (2) in emergency surgery lowering dose of premedication; (3) when necessary, administering a vasopressor. Do not use in hyperactive and hyperexcitable patients. Pargyline may unmask severe psychotic symptoms where emotional problems pre-exist. Use cautiously in Parkinsonism, especially with antiparkinsonian agents. In prolonged therapy, examine for change in color perception, visual fields, fundi and visual acuity. Also, prolonged therapy has made certain patients refractory to nerve blocking effects of local anesthetics.

Methyclothiazide: Use cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery thiazide may reduce vasopressor response and increase tubocurarine response. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia). Give supplemental chloride if hypochloremic alkalosis occurs and supplemental potassium if hypokalemia occurs (especially in digitalized patients). Thiazides may decrease serum P.B.I. without signs of thyroid disturbance.

Adverse Reactions — Pargyline: Orthostatic hypotension and associated symptoms, mild constipation, fluid retention, edema, dry mouth, sweating, increased appetite, arthralgia, nausea, vomiting, headache, insomnia, difficult in micturition, nightmares, impotence, delayed ejaculation, rash, purpura, weight gain, hyperexcitability, increased neuromuscular activity and other extrapyramidal symptoms. Drug fever is extremely rare. Reduction in blood sugar and hypoglycemic effects are possible. Congestive heart failure has been reported in a few patients with reduced cardiac reserve.

Methyclothiazide: Blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, blood sugar or serum uric acid (gout may be induced); anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice and pancreatitis. Cutaneous vasculitis in elderly patients has been reported with other thiazides.

If side effects are severe or persist, reduce dosage or withdraw drug. 804438R

FIGHTING CANCER WITH FILMS...

...is not news. What's news is that we've embarked on the most ambitious film program *for professional medical audiences* ever launched against a single disease. A half-million dollar film project is underway—with technical advice from the nation's leading medical authorities.

Five of these films are available now—
CANCER IN CHILDREN, DIAGNOSIS AND MANAGEMENT OF CANCER OF THE COLON AND RECTUM, ORAL CANCER, NURSING MANAGEMENT OF THE PATIENT WITH CANCER, and THE DENTIST AND CANCER. The balance will be released in 1967-1968.

As pioneers in the usage of medical films, we know their value as teaching tools. Our Units across the country know, too. Films are a vital part of their professional educational programs. We hope you will contact *your* local ACS Unit about this outstanding new series.

AMERICAN CANCER SOCIETY®

Grand Rounds

Isoniazid Prophylaxis

OLE M. JERDE, M.D.
Minneapolis, Minnesota

"There are many small areas today where tuberculosis has been eradicated, and with no reason to assume it is inevitable that tuberculosis will appear again in those areas, or if it does, that it cannot be contained and eliminated again and rather rapidly. Why is it unrealistic, then, to assume that we can enlarge the perimeter of each of these lacunae until their borders touch each other and they coalesce into an ever-expanding sea, until finally the last islands of the residual strongholds of tuberculosis have been engulfed, and the last infected person has disappeared?" *James E. Perkins*[1]

While Dr. Perkins' vision has not been fulfilled and perhaps will not be for some time to come, gains have been made in the eradication of tuberculosis; however, in several socio-economic and ethnic groups the disease is still a serious health problem. There has been a continuous decline in tuberculosis mortality rates from the turn of the century to the present, with a sharp decline following the introduction and use of drugs,[2] particularly Isoniazid. Naturally, the next question to arise was whether Isoniazid would be effective in the prevention of tuberculosis as well as in the treatment.

The purpose of this paper is to discuss the chemoprophylaxis of tuberculosis: primary chemoprophylaxis, the use of Isoniazid in exposed but uninfected individuals, and secondary chemoprophylaxis, the treatment with Isoniazid in the tuberculin-positive individual.[3] In addition, attention will be given to the tuberculin-positive individual who falls into the increased-risk category of developing active pulmonary tuberculosis.

Prior to clinical trials, animal studies were carried out to demonstrate whether Isoniazid was effective in the prevention of tuberculosis. Using monkeys, Schmidt[4] showed that Isoniazid therapy could prevent the disease and that this protection lasted for from four to six months following cessation of therapy. Ferebee and Palmer,[5] using guinea pigs, also demonstrated

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, December 5, 1967.

that Isoniazid could prevent active tuberculosis. Protection was inadequate when given at 1 mg. Isoniazid/kg. per day; however, at 5 mg./kg. per day and at 25 mg./kg. per day the animals were completely protected. Following cessation of therapy at ten weeks the animals were protected for a total of 26 weeks. It also appeared that the animals treated with 5 mg./kg. per day developed more immunity than those treated at the higher dosage level. Omoedi Zorini[6] demonstrated the effectiveness of Isoniazid in the prevention of bovine tuberculosis in calves.

Certain individuals have an increased probability of developing tuberculosis. These individuals may be divided into the following categories:[3,7,8]

I. Exposed Tuberculin-Negative Individuals.
II. Positive Tuberculin Test but No Evidence of Clinical Disease.
    A. Recent converter.
    B. Positive skin test in childhood and young adulthood or positive tuberculin test with excess or continued exposure.
    C. Strong tuberculin reaction.
    D. Positive tuberculin reactors in mental institutions.
    E. Positive skin test associated with other conditions such as steroid therapy, uncontrolled diabetes, silicosis, sarcoidosis, lymphomas and leukemia, pregnancy, malnutrition (including alcoholism), post-gastrectomy, and measles or whooping cough.
III. Positive Tuberculin Test with Roentgenograph Findings.
    A. No drug therapy.
    B. Inadequate drug therapy.
    C. Far advanced disease.
    D. Changing roentgenographic pattern.

Results of Clinical Trials

In all the trials to be discussed, unless otherwise stated, a positive tuberculin test was a reaction greater than 5 mm. induration using intermediate strength Purified Protein Derivative Test. When placed on Isoniazid the individual was given therapy at an average dosage of 5 mg./kg. per day up to 300 mg. daily.

Exposed Tuberculin-Negative Patient

All persons exposed to a patient with active tuberculosis must be given prophylactic Isoniazid while exposure exists. Management of the tuberculin-negative patient recently exposed to tuberculosis may be handled in different ways.

In a double blind study on tuberculin-negative patients, Egsmose et al.[9] showed a 7% decrease in the tuberculin conversion in those patients on prophylactic Isoniazid therapy compared with the control group. The patients had received Isoniazid 5-10 mg./kg. per day for a period of one year and had been observed for two to four years. He also noted a significant decrease in the rate of development of active pulmonary tuberculosis in those patients on prophylactic Isoniazid therapy (Table 1).

Ferebee and Mount[10] found that Isoniazid was effective in the exposed tuberculin-negative individual. Five cases of primary tuberculosis developed in the Isoniazid group and 16 in the placebo group during the treatment year. Some of the patients on Isoniazid may have been infected at the time therapy was initiated.

Dormer et al.[11] used Isoniazid in infants of mothers who had active tuberculosis and were in various stages of therapy. The mothers and infants were kept in an open ward, and most infants were breast fed. The infants were given 25 mg. of Isoniazid syrup twice daily, increased to 50 mg. twice a day at six months of age. There were no cases of tuberculosis found in the infants during the observation period.

These studies would indicate that Isoniazid is of benefit in the exposed tuberculin-negative patient. An alternate route would be to observe these patients closely with repeated skin tests and treat them upon conversion of the skin test.[12] However, if the family is large with both positive and negative reactors, it would be simpler and probably more effective to treat the entire family with Isoniazid.

The person who has had an extremely large exposure to tuberculosis, such as may occur in a laboratory accident or in resuscitation of a tuberculous patient, should be placed on prophylaxis, with skin tests repeated every three months.

Positive Tuberculin Test but No Evidence of Clinical Disease

A. Recent Converter

The recent tuberculin converter falls into the high-risk area of developing pulmonary tuberculosis. However, the exact time of conversion is frequently unknown, making it difficult to establish or interpret statistics.

Chiba et al.,[13] in a controlled double blind study composed of recent tuberculin converters, gives us some idea as to the prognosis of this group as well as the effect of prophylaxis. Two hundred seventy-four patients in his group were treated with either Isoniazid or a Isoniazid-Paraaminosalicylate combination, while 274 were on placebo alone for the same one-year period. In a period of observation ranging from six to twelve years, nine of the treated group and 23 of the control group developed pulmonary tuberculosis. This work led to a large-scale study by the same authors in which over 4,000 patients were treated and then observed for a one- to five-year period. In terms of person years, 0.24% of the treated group and 1.25% of the control

TABLE I

Significance of Difference in Incidence Rates Observed in Control and Isoniazid Groups

Initial Status	During first year of study	Control Group		Isoniazid Group		Significance of the difference at the 5% probability level
		Incidence rate (%)	SE	Incidence rate (%)	SE	
Tuberculin non-reactors	Tuberculin conversion	13.19	3.13	5.68	2.07	Significant
	Development of pulmonary lesions	4.32	1.95	1.86	1.09	Not significant
	Excretion of tubercle bacilli	3.78	1.53	0.00	0.00	Significant
Tuberculin reactors	Excretion of tubercle bacilli	1.60	0.87	1.04	0.72	Not significant
Pulmonary lesions (active & inactive)	Excretion of tubercle bacilli	21.43	8.08	0.00	0.00	Significant

Egsmose et al.[9]

group developed pulmonary tuberculosis.

In another series by Groth-Petersen et al.[14] of patients with positive tuberculin and negative chest x-rays, the risk of developing pulmonary tuberculosis was 27 per 100,000.

Ferebee and Mount,[10] in a study involving 25,512 household members of an index case, found 479 with active tuberculosis or 19 per 1,000. It is not known how long these may have been active, but probably many were recent converters. Of those individuals who had a positive skin test and negative chest x-rays, 16 in the placebo group and four in the Isoniazid group developed extra-pulmonary tuberculosis. Also 62 patients developed pulmonary tuberculosis in the placebo group compared with 14 in the therapy group. The risk was well correlated with the skin test, ranging from 8.3 per 1,000 for those with 5-9 mm. positive reaction to 20 per 1,000 for those of 20 mm. or more induration.

Meyers et al.[15] followed a group of 149 children who were known recent converters, with a mean age of 14.6 years at time of conversion. Eleven (8.5%) had developed tuberculosis with a mean duration from skin test conversion to active tuberculosis of four years with a range of a few months to about 25 years.

In another publication Meyers et al.[16] reported 195 children, ages six to 12, who were known converters. Eleven (7.4%) have developed clinical disease with four deaths. Onset of clinical disease following conversion ranged from three months to seven years. One patient was found to have advanced disease 24 years after conversion; however, as she had not been followed, the time of onset of clinical disease was not known.

In another review[17] the rate of clinical disease in the tuberculin-positive patient is estimated to be 5% over an indefinite period of time.

Steinfield and Cohen[18] have advocated Isoniazid therapy at 10 mg./kg. per day for two years' duration. They have treated all contacts in the household regardless of skin test, and in 442 patients who have been followed for over three years none have developed clinical tuberculosis.

B. Positive skin test in childhood and young adulthood or positive tuberculin test with excess or continued exposure.

Meyers et al.[19] followed a group of 750 children with positive skin tests who were ages one to six at the time the study was instituted. Most of them were followed for several years. Of the group that had positive skin tests with tuberculous primary infiltrates, seven of 151 patients died from tuberculosis. An additional seven developed clinical disease and were treated with satisfactory long-term survival. Meyers also reported on 599 children who had a positive tuberculin test but normal chest x-rays. Of this group 41 developed clinical tuberculosis with 15 deaths.

In another of Meyer's studies[16] involving the six-to-12 age group, of 1,247 tuberculin-positive children who were followed, 25 deaths (2%) occurred.

Mount and Ferebee[20] reported a double blind study of children with primary tuberculosis and found that the risk of developing complications was significantly higher in those under six years of age. They also found Isoniazid to be very effective, especially in extrapulmonary complications. Of those children on Isoniazid, 30 developed pulmonary complications compared with 46 taking the placebo. Extrapulmonary complications occurred in 31 cases on placebo compared with only two cases in the Isoniazid-treated group.

During a follow-up period of two years, eight patients who had been on the placebo developed complications compared with four who had been taking Isoniazid. This would indicate that Isoniazid had some prolonged beneficial effect in addition to the observations while on therapy.

One can only concur with Mitchell[8] that all patients under five years of age with a positive skin test should be treated.

It has often been thought that children in the six-to-12-age group had an increased resistance to tuberculosis. While this may be true, 2% of Meyers' series[16] died of their disease.

It has been felt that since there is an increased susceptibility to tuberculosis during puberty and adolescence, prophylaxis during this period should be recommended.[7] Steinfeld[18] suggests treating all tuberculin-positive individuals 20 years of age or younger. Meyers' studies,[15] however, did not show an increased susceptibility in this age group. He felt that mortality and morbidity studies reflected natural progression of the disease in a person infected at a younger age.

In a group of tuberculin-positive young adults in a university in Poland a double blind study showed the effectiveness of Isoniazid prophylaxis. Of the placebo group 2.2% developed tuberculosis, while none in the therapy group did.[21]

Not infrequently an adult patient is discovered who has a positive skin test along with a negative x-ray, but there have been no double blind studies in this group of patients.

All contacts of an active case of tuberculosis are considered high risk and should receive chemoprophylaxis. Gregg and Kuemmerer[22] in 1961 investigated the contacts of 102 index cases of tuberculosis and found 29 active cases on first examination, with an additional 21 cases on subsequent testing. Prophylactic chemotherapy was given to all contacts with a 56% decrease in the incidence of active tuberculosis among household contacts.

Omoedi Zorini[6] reported that 2.14% of his household contacts which served as controls developed tuberculosis, compared with 0.13% of those treated with Isoniazid.

Egsmose et al.,[9] in a study of household contacts, noted a 1.6% activation rate among the controls as compared with 1% in those on Isoniazid therapy; but he did not consider this a significant decrease.

Comstock,[23] in a double blind study from Alaska, reported an incidence rate of active tuberculosis of 1.36% per year in the control group compared with 0.43% in the Isoniazid group, and stated that Isoniazid showed a 64% reduction in the number of expected cases.

Ferebee and Mount,[10] in examining over 25,000 contacts of index cases, found 479 patients with active tuberculosis or 19 per 1,000. All contacts were then placed on chemoprophylaxis for one year. Pulmonary tuberculosis developed in adults in 62 cases on placebo and in 14 patients on Isoniazid therapy.

In a follow-up study from Alaska, Comstock et al.[24] reported an incidence rate of 4.67% in the placebo group compared with 1.9% in the Isoniazid-treated group. The risk of tuberculosis developing during the study period was greatest among positive tuberculin reactors and young adults.

Horwitz et al.[25] reported a double blind study involving 8,081 adults from Greenland, all of whom were assigned to either the placebo or the Isoniazid therapy group regardless of their tuberculin status. Their studies showed an incidence rate for the first year in the control group of 19 per 1,000 com-

pared with 13 per 1,000 in the Isoniazid group. During a six-year follow-up, the Isoniazid group continued to show a beneficial effect, with a decreased incidence rate compared with the placebo group (Table 2).

TABLE 2
Incidence of Respiratory Tuberculosis by Year in Follow-Up Period

Year in follow-up period	Placebo		Isoniazid	
	No.	Annual No. per 1,000	No.	Annual No. per 1,000
1st	73	19	53	13
2nd	68	17	42	10
3rd	55	14	40	10
4th	45	12	45	11
5th	52	13	33	8
6th	30	8	25	6
TOTAL	323	14	238	10

Horwitz et al.[25]

A study was conducted by Mount and Ferebee[26] of household contacts of previously active cases, where the exposure had occurred from a few months to several years prior to starting the study. Examination of these contacts revealed ten with active tuberculosis or a rate of 3.5 per 1,000, again indicating the importance of follow-up. Among the placebo group nine developed active tuberculosis or a rate of 6.7 per 1,000, while three in the Isoniazid group developed clinical tuberculosis. Eight of the nine patients in the placebo group had had positive tuberculin tests at the initiation of the study.

C. Strong Tuberculin Reaction.

As mentioned previously, Ferebee and Mount[10] observed a correlation between the extent of the tuberculin reaction and the risk of developing tuberculosis.

The group from Denmark[14] also found that the size of the reaction was important in relation to the risk of developing tuberculosis, particularly in the younger age groups. For the age range 15-24 years, 6-11 mm. induration was associated with an incidence of 24 per 100,000, while with a reaction from 18-23 mm. they found an incidence of 87 for 100,000.

Comstock et al.[24] did not concur. They noted that the greatest risk occurred in those who were originally negative, with little difference in incidence among the positive reactors. Others[8,21] advocate therapy of the strong reactor.

D. Positive Tuberculin Reactors in Mental Institutions.

Ferebee et al.[27] did a study concerning the effectiveness of Isoniazid in preventing active tuberculosis in several U.S. mental institutions, involving over 25,000 patients. During the medication year which includes the three months following cessation of therapy, 21 in the placebo group developed active tuberculosis compared with four who had received Isoniazid. Three of those four had abnormal x-rays at the beginning of the study but responded well to Isoniazid therapy. The reason for becoming active while on the drug is unknown. Isoniazid prevented three fourths of the cases that would have developed had the drug not been given.

E. Positive Skin Test Associated with Other Conditions Such as Steroid Therapy, Uncontrolled Diabetes, Silicosis, Sarcoidosis, Lymphomas and Leukemia, Pregnancy, Malnutrition (Including Alcoholism), Post-gastrectomy, and Measles or Whooping Cough.

Development of tuberculosis in the patient with silicosis is a frequent and severe complication. Monaco[28] reported that 98% of patients with silicosis had a positive tuberculin reaction and that 63% would die of tuberculosis. In a controlled study he treated patients with Isoniazid 10 mg./kg. per day or placebo for three months, alternating with three months of rest for a period of two years. He found that 0.75% of the treated group developed active tuberculosis compared to 10.21%.

Omoedi Zorini[6] reported a study involving 788 cases of silicosis with either positive tuberculin or exposure to tuberculosis, who were treated for a period of two years. Of 370 controls, 7% developed tuberculosis compared with 1.14% of the therapy group.

There is increased risk of tuberculosis in the patient who has had gastric surgery. Chofnas and Love[29] reported on 250 patients, of whom 17 (6.8%) had had surgery, thirteen of them gastric surgery prior to the onset of pulmonary tuberculosis.

Waingortin and Lorge[30] presented a series of 27 cases of tuberculosis associated with gastrointestinal disease, twelve of them after surgery for peptic ulcer. Four patients developed symptoms after thoracoplasty. In seven pulmonary tuberculosis preceded the onset of peptic ulcers. An additional four had ulcer symptoms preceding the onset of tuberculosis; however, these patients had had only medical therapy. The authors noted that physical and emotional stress were very prominent in this group of individuals.

Borner[31] observed an increased incidence of tuberculosis in his series of post-gastrectomy patients and also noted a much higher death rate in these patients. While various factors such as starvation, malabsorption, metabolic abnormalities, stress and poor hygiene have been postulated as etiologic factors, no true cause for this increased incidence of tuberculosis has been found. While Borner did not find any definite studies showing the benefit of prophylaxis in this group, certainly they should be observed closely with repeated chest x-rays and possibly be considered for prophylactic therapy.

Management of the pregnant tuberculosis patient presents a unique problem; studies in the past have been somewhat contradictory regarding the effect of pregnancy upon tuberculosis. In previous years it was thought that tuberculosis had an adverse effect on pregnancy; at times abortion was even recommended and performed.[32]

Rosenbach and Gangemi[33] presented their results in a series of 150 patients with active tuberculosis who were observed during 241 pregnancies. While 23 patients showed progression of tuberculosis, most of these refused to follow medical advice. Nineteen showed regression during pregnancy and the postpartum period. The authors concluded that pregnancy had little effect on the progression of tuberculosis.

Pridie and Stradling[34] reported on 103 pregnancies in 72 patients with pulmonary tuberculosis, twenty of whom relapsed some time during the pregnancy or in the succeeding year. No relapses occurred in the group given chemotherapy during pregnancy, about half of these having received no chemotherapy previous to the pregnancy. All the relapses occurred in the group not given chemotherapy during pregnancy, 17 of whom had never

had chemotherapy for the disease. Pridie et al. therefore concluded that relapse could be effectively prevented during pregnancy by chemoprophylaxis (Table 3).

TABLE 3
Relapse and Chemotherapy

	Chemotherapy During Pregnancy			No Chemotherapy During Pregnancy		
	Initial Chem.	No Initial Chem.	Total	Initial Chem.	No Initial Chem.	Total
Relapse	0	0	0	3	17	20
No relapse	22	6	28	21	34	55
Total	22	6	28	24	51	75

Pridie and Stradling[34]

Rovinsky and Guttmacher[32] suggest the following when dealing with pregnancy in tuberculosis: If the patient has a healed Ghon complex on x-ray and a positive skin test but no other evidence of the disease they would withhold all therapy and observe only. If the patient has had pulmonary tuberculosis but is now judged inactive they recommend prophylaxis beginning with the seventh month of pregnancy. A recent skin converter should be given Isoniazid therapy. They also suggest that a strongly positive tuberculin reactor be given prophylaxis.

Grzybowski[12] recommends chemoprophylaxis in tuberculin-positive children who develop measles and whooping cough.

While statistics are lacking it is well known clinically that prolonged steroid therapy may reactivate quiescent tuberculosis. Animal studies and clinical reports are discussed in a review by Johnson and Davey.[35] Many studies showed that steroids have an adverse effect on the tuberculous animal; however, others found no difference. Case reports indicated that while an occasional patient improved, the majority became worse while on steroids. Others[36,37] reported patients with various diseases including rheumatoid arthritis, sarcoiditis, lupus erythematosus and polyarteritis who developed tuberculosis while on steroids. All patients with a positive skin test or inactive tuberculosis should receive prophylaxis while on steroids. The patient with sarcoidosis should also receive Isoniazid therapy whenever long-term steroids are given.

Nutrition is an important factor in many diseases, including tuberculosis. Keys et al.[38] studied the state of nutrition in several countries during World Wars I and II. While many other factors, including rest, sanitation, overcrowding, poor medical care for the sick, and better housing are significant, changes in the incidence of tuberculosis can be closely correlated with the diet. Quality as well as quantity were considered important factors.

Patients with lymphoma, especially Hodgkin's disease, and leukemia have an increased incidence of tuberculosis. Parker et al.[39] reported that 30% of patients with Hodgkin's disease also had tuberculosis. Arden and Rottino,[40] in a series of 162 autopsies on patients with Hodgkin's disease, found that five had died (3%) of miliary tuberculosis. In two of these, Hodgkin's disease had been completely arrested. The marked difference in incidence in these series may reflect the overall decrease in the incidence of tuberculosis. Arden et al.[40] felt that steroids or irradiation therapy had no effect on the development of tuberculosis. Haynes and Begg[41] reported two patients with lymphoma who died of miliary tuberculosis following therapy with steroids and/or

chemotherapeutic agents. Morrow and Anderson[42] reported leukemia or lymphoma in a series of patients exposed to the atomic bomb in 1945. Of patients with chronic myelogenous leukemia 23% had tuberculosis. While there were only twelve patients with myelofibrosis, four of these had miliary tuberculosis. There was no increase in tuberculosis in the acute leukemias.

It has long been known that diabetes and tuberculosis are frequently associated, for reasons still not evident. Halden and Hiltz[43] reported 11% of their tuberculosis patients to have diabetes and also noted that the diabetes was more severe in those patients with far advanced tuberculosis. Of 13 patients who reactivated, eleven were discovered to have diabetes at the time of reactivation. In a series of young men with tuberculosis, Nichols[44] found that 22% had diabetes or abnormalities in glucose tests.

Positive Tuberculin Test with Roentgenographic Findings

There are large numbers of individuals who have had clinical tuberculosis and who have abnormal x-rays. Of this group it is estimated that 10,000 will relapse annually.[45] Depending upon adequacy of treatment, state of disease, etc., some of these have a much higher risk of developing active tuberculosis, being a hazard to themselves as well as to others in their environment. The balance of this paper will be concerned with identifying those of greatest risk so that close observation and appropriate therapy may be given.

Phillips[46] reported a series of 312 tuberculous patients who were followed for three years after discharge from the hospital, only two thirds of whom had received some form of chemotherapy. During the three-year period he noted that 80 patients (25.6%) had clinical relapses. This was well correlated with the extent of clinical disease, with 14% occurring in the minimal category, 24% in the moderately advanced group, and 32% in those with far advanced tuberculosis.

In a series of 112 patients Phillips[45] followed for 15 years he found that relapse had occurred in 47 patients, 17 of whom had had more than one reactivation. Eighty per cent had never received chemotherapy, and the remaining twenty per cent had received inadequate chemotherapy.

The effectiveness of adequate chemotherapy in preventing relapse is demonstrated in a series of 109 patients followed for six years after hospital discharge[47] (Tables 4 and 5).

TABLE 4

Effect of Chemotherapy Regimen

Regimen Employed	No. of Patients	No. of Relapses	Relapse Incidence
Isoniazid combinations	72	15	7%
Streptomycin combinations	15	2	13%
Mixed combinations	7	1	14%

TABLE 5

Duration of Chemotherapy

Total Period Chemotherapy Employed	No. of Patients	No. of Relapses	Relapse Incidence
Less than 18 months	14	3	21%
Less than 2 years	38	6	16%
Two years or more	56	2	4%
Three years or more	17	0	0%

Phillips, S.[47]

Best results were obtained with the use of Isoniazid combinations in which an incidence of 7% occurred. Combinations of other drugs were associated with a 14% relapse rate. Duration of therapy was important, with a 21% relapse in those treated less than 18 months compared with 4% in those treated two years or more.

Comstock[48] presented a series of 1,008 cases of inactive but untreated tuberculosis which he followed for up to ten years. Sixty-eight patients (6.7%) developed active clinical disease, most of which occurred during the early part of the observation period. The risk was much greater for Negroes compared with Whites; it was also significantly higher in the advanced disease group. For example, the incidence in Negroes with advanced disease was greater than 30%. In the younger age group those with minimal and suspected disease were also high risk.

Fuchs[49] reported on 3,214 patients, some of whom had been followed in excess of 20 years. In those with adequate drug treatment there was a 2% risk of reactivation over a five-year period. The risk of reactivation was three and one-half times greater in those with no or inadequate chemotherapy, while the patient who was uncooperative and inadequately treated showed a 37.5% risk of reactivation of the disease. The patient with a changing x-ray pattern also is a high risk.

Katz et al.[50] used prophylactic Isoniazid in a group of 247 patients with inactive tuberculosis. They received 300 mg. per day for two years and were observed for a period of four years following cessation of therapy. During the treatment period Katz found that Isoniazid had a significant effect in preventing reactivation with an additional protective effect which lasted about two years after cessation of therapy.

Chiba et al.[13] also used prophylactic Isoniazid in a group with inactive pulmonary tuberculosis. The control group showed a relapse of 4.5% compared with a 0.72% relapse rate in the treated group, demonstrating the beneficial effect of prophylaxis.

Ferebee et al.[27] found an activation rate of 13 per 1,000 in a control group compared with 2.5 per 1,000 in a treated group.

Isoniazid in Prophylaxis

Ferebee[10] notes that Isoniazid is an ideal drug for the chemoprophylaxis of tuberculosis. It is extremely effective, safe, inexpensive, and well tolerated. Side reactions to Isoniazid can be divided into two categories: hypersensitivity and toxicity.[51] The most frequent reactions involve the nervous system as well as the gastrointestinal tract. Various reactions including fever, skin reactions, hepatitis, convulsions, ataxia, optic atrophy, toxic encephalopathy along with agranulocytosis have been reported, but fortunately are extremely rare. In the clinical studies[9,10,18,23,25,26,27] all studies reported less than 2% side reactions, and most studies reported less than a 1% incidence. Certainly the patient should be observed for evidence of pyridoxine deficiency and treated for it if present. Elderly or malnourished patients should receive this drug routinely.

Kapur et al.[52] reported that one patient developed resistant tubercle bacilli following Isoniazid prophylaxis. Many observers were concerned about this possibility. While sensitivity studies were rarely carried out, drug resistance was not found to be a clinical problem.[23,24,25,27]

Summary

Isoniazid is found to be a very effective agent in the chemoprophylaxis of tuberculosis. It is recommended that those individuals who have an increased risk of tuberculosis be placed on at least one year of Isoniazid prophylaxis. Active tuberculosis must be excluded by appropriate means prior to instituting prophylactic Isoniazid therapy.

What's New?

Abbott Laboratories— Nuclear medical instruments for small hospitals, clinics and physicians' offices.

Three new instruments designed to make radioisotopes testing available in smaller hospitals and clinics have been announced by Abbott Laboratories. These instruments will permit tests of thyroid function, red blood cell mass, plasma volume and latent iron-binding capacity by small, self-contained units. The three models include two well counters and one scaler analyzer. Each unit measures 12-1/2 by 13 inches by 4-1/16 inches high and weighs from 25 to 35 pounds. Costs range from $2300 to $2700. Further information on the LOGIC series counting systems is available from Abbott Laboratories, North Chicago, Illinois, 60064.

Wyeth Laboratories— A new oral contraceptive named "OVRAL" has been introduced in the United States by Wyeth Laboratories. This pill combines an estrogen with a progestogen, norgestrel. Norgestrel is a synthetically prepared steroid. This new oral contraceptive is presented in an attractive plastic dispenser with a printed "memory" listing the days of the week to assist the patient with proper dosage.

Winthrop Laboratories—Small intravenous doses of a new non-narcotic analgesic were found effective in reducing postoperative pain, in lowering the overall need for analgesia and in shortening the duration of hospitalization. The analgesic, Talwin, brought satisfactory pain relief rapidly and safely in 86.9 percent of the patients given injections.

Glenbrook Laboratories—Aspirin is well known for pain relief in the treatment of arthritis. Recent experiments, however, have shown that the salicylates are also anti-inflammatory, aiding joint movements and grip strength in cases of rheumatoid arthritis.

Derivatively Speaking

Sacrum—from Latin *sacer* (sacred).

"Everything looks fine,
but we should do something about that extra weight you're putting on."

Get them while they're easily reversible.

Obesity doesn't happen suddenly. This insidious process has its beginning—and the chances of reversing it are better—during the *first 10 to 15 pounds of weight gain.* When a new dietary pattern must be established, consider the adjunctive use of BAMADEX SEQUELS. Combining the proven *anorexigenic* action of d-amphetamine with the *tranquilizing* effect of meprobamate, BAMADEX SEQUELS controls appetite throughout the day, usually with a single capsule daily.

Contraindications: Dextro-amphetamine sulfate: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.
Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.
Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness. Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

The Health of the Nation

A special summer lecture series sponsored by the University of Minnesota Hospitals and local member hospitals of the Council of Teaching Hospitals, American Association of Medical Colleges (i.e., Miller, Ramsey County, Hennepin County, Veterans, Mt. Sinai) will be held at the University of Minnesota Health Sciences Center during the summer months. The objective of the meeting is to bring together community leaders and health professionals to focus on major health issues of the day.

This will be an invitational conference with participants including representatives of medical staffs, boards of trustees and hospital administration from the metropolitan area. In addition, representatives will be in attendance from various local and state health organizations as well as members of the faculties of the health science units. The meetings, which will be held in Mayo Auditorium at 12:00 noon. Any individuals who do not receive an invitation and would like to attend some of these sessions should contact C. Thomas Smith, Jr. at Box 605, University of Minnesota Hospitals.

Friday Noon Summer Series
Mayo Auditorium

serous otitis media
an original article
by Robert H. Lofgren, M.D.

the complaining earache... key to serous otitis media

Robert H. Lofgren, M.D.
Associate Surgeon, Massachusetts Eye and Ear Infirmary, Boston, Massachusetts

Serous otitis media is probably the most common ear problem in children, especially in the wintertime. Diagnosis is usually easy in adults, but may be quite difficult in children, especially the very young child where one has to depend almost entirely on the physical findings.

The symptoms of serous otitis are a fullness in the ear, a mild hearing loss and mild earache. The earache can best be described as a "complaining earache" instead of a "screaming earache" as found in purulent otitis media. A young child may be irritable and pull at the ear. In milder cases, and as the ear recovers, gurgling and popping noises can be heard in the ear.

On examination one may see a yellow tympanic membrane and if a fluid level is present the diagnosis becomes easy. However, the eardrum may be dull gray, or slightly pink, or even perfectly normal. Pneumomassage using a Siegle otoscope or a closed-head electric otoscope must be done on both ears, otherwise the diagnosis will be frequently missed. Attempted movement of the drum with the pneumatic otoscope produces either a sluggish motion of the drum or no motion at all instead of the easily movable normal drum. The Rinne test is negative and there is a 15-20 decibel conductive hearing loss. The bone conduction may be better than normal and an air-bone gap may exist even with the air conduction within normal limits. Occasionally one finds a false nerve deafness on the audiogram when thick glue-like fluid causes immobility of both the oval and round window. Both conditions return to normal when the fluid is removed, but they make the interpretation of screening audiograms very difficult.

There is no single cause for serous otitis. One factor always present is blockage of the eustachian tube, but this alone is not enough to produce fluid. There must also be an inflammatory reaction. Blockage of the eustachian tube may be caused by many conditions. In children the most common cause is enlarged adenoids. In the summer the next most common cause is allergy. Upper respiratory infections or influenza are common causes in the winter. Nasal allergy, acute and chronic sinusitis, nasal septal deformity and cleft palate can all cause eustachian tube obstruction. Some children may have a congenitally small eustachian tube, but fortunately they usually "grow out of the problem."

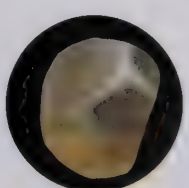
The first sign of a nasopharyngeal tumor is often a serous otitis. One must always rule this out in any adult who later in life develops repeated or persisting serous otitis. Causes sometimes overlooked are nasogastric tubes after surgery, simple obesity and cardiorenal disease, which may produce congestion in the mucosal lining of the eustachian tube. In recent years we have been seeing a new cause—acute otitis media, where the patient is adequately treated with antibiotics but where drainage has not been

established either through the eardrum or down the eustachian tube. A sterile exudate is left in the middle ear.

The inflammatory response may be caused by a marked negative pressure as in air otitis from flying, or it may be from a mild bacterial or viral infection in the middle ear. Serous fluid is a good culture medium and will frequently go on to purulent otitis media, especially if the original blockage was caused by an infectious process such as acute rhinitis or adenoiditis. When the infection heals there may be scarring in the middle ear mucosa. Mucous glands develop in this tissue and pour out a thick mucoid material. This ear usually looks normal until a pneumatic otoscope is used. The objectives in treating serous otitis are to remove the obstructing agent and to provide drainage from the middle ear. Often this can be accomplished by decongestants and nose drops. If large obstructing adenoids are present they should be removed. Sinusitis should be treated with oral decongestants or nose drops, plus antibiotics where indicated. Nasopharyngeal tumors should be treated. Allergies should be treated with antihistamines and, where indicated, by desensitization.

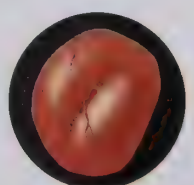
If the fluid does not clear with medical treatment within a week or two, a myringotomy should be done. If there is a question of active infection or if the fluid looks purulent, as is seen at the conclusion of acute otitis, cultures are taken. On adults this can be done in the office without anesthesia. It is no more painful than an intravenous needle for a blood test. A good safe topical anesthetic has a tremendous psychological value to the patient. Children under the age of 1 require no anesthesia. Between the ages of 1 and 3 anesthesia is not absolutely essential although a general anesthetic may be used to avoid the child's possible mistrust at follow-up examinations. I usually do the myringotomy at the same time as the adenoidectomy if the adenoids are enlarged. Once drainage has been established with decongestants or by myringotomy, positive pressure inflation of the middle ear is invaluable in forcing out the serous fluid and keeping it from reforming. The patient can do this himself by performing the Valsalva maneuver. This should be done several times a day, by taking a deep breath, holding the nose and blowing hard against the closed lips for a second or two.

In resistant cases where the fluid reforms as soon as the myringotomy heals, small polyethylene tubes are inserted through the myringotomy site. Insertion of the tubes, even in adults, usually requires an anesthetic. Good anesthesia can be obtained by infiltrating the canal wall with a local anesthetic, using a #27 needle. Once inserted the patient has no sensation of the tubes' presence. Be careful to caution the patient or parents not to allow any water to get into the ear canal while a myringotomy is open or a tube is in place. Water can be kept out by a pledget of lamb's wool in the ear canal or a cotton pledget thickly coated on the outside with petroleum jelly. I check these patients a week after a myringotomy to be sure it is healed and at two month intervals until the tubes have fallen out, usually within three to six months after insertion.



The mucoid type of fluid is so thick and tenacious that it is appropriately called a glue ear. It is aspirated only with difficulty through the eardrum, and occasionally must be removed through a tympanotomy. This thick, glue-like fluid is prone to recur, as the myringotomy usually heals long before the mucous membrane has returned to normal. Repeated myringotomies, as many as ten or twenty, were formerly required for this condition. Now polyethylene tubes are inserted initially when this thick, glue-like material is found. At times a subacute mastoiditis may accompany the serous otitis, which will necessitate a simple mastoidectomy before the condition can be eradicated. Usually the thin serous fluid readily responds to decongestants or to a myringotomy and removal of the eustachian tube obstruction. Occasionally, however, even serous fluid will repeatedly reform. For this, resection of the tympanic plexus of nerves which lies on the promontory of the middle ear has been carried out, as the tympanic branch of the glossopharyngeal nerve is the secretomotor nerve to the ear.

Failure to diagnose serous otitis is the most common cause of the recurrent, almost continuous otitis me-



Otoscopic Views

Acute Purulent

Chronic Serous

dia seen in young children. In these cases a myringotomy will frequently provide a long-term cure without adenoidectomy or any other surgery. Failure to do this may allow the condition to go on to acute or subacute mastoiditis. Adhesive otitis media with scar tissue binding down the ossicles or tympanosclerosis may also result with permanent impairment of hearing. The prognosis for hearing with adhesive otitis or tympanosclerosis is usually poor. If the adhesions are removed, they reform, and the same is frequently true of tympanosclerosis even after a tympanoplasty. For many of these people a hearing aid is the only solution. The constant negative pressure in long standing serous otitis media may draw in either Schrapnell's membrane or the posterior superior portion of the eardrum forming a pocket to cause a chronic otitis media with cholesteatoma, which may not become apparent until twenty or thirty years later.

The non-medical complications of improper diagnosis or treatment may be even more serious. The irritable child, the frequent bouts of acute purulent otitis media with pain and fever, the expense of antibiotics and doctors, and the time lost from school or work affect the entire family.

In summary, serous otitis has many causes. There is a blocking of the eustachian tube and an inflammatory reaction in the middle ear mucosa, the latter usually caused by a mild infection. The treatment is to provide immediate drainage by decongestants and where necessary, by a myringotomy. The obstructing agent must be removed by surgery if it is adenoid or by oral decongestants, and antihistamines or nasal spray if it is an upper respiratory infection or allergy. Occasionally resistant cases require plastic tubes placed through the eardrum or other more radical surgery. Failure to treat properly leads to hearing loss which may be permanent, repeated acute otitis media or possibly even chronic otitis media with cholesteatoma.

THE TINY FLAWS IN MEDICAL DESIGN CAN KILL

The number of patients who have been injured and killed by electrical shocks in hospitals has stimulated several organizations to seek ways to prevent these accidents. Efforts to set safety design standards are being made by such professional groups as the Safety Committee of the Instrument Society of America, the Corresponding Committee of the IEEE, and the Standards Committee of the Association for the Advancement of Medical Instrumentation. In Congress a bill has been introduced in the House of Representatives to create a national commission that would study the quality controls and manufacturing procedures of companies that make medical instrumentation equipment.

The reason for all this concern is the growing number of injuries from malfunctioning and poorly designed equipment. At one midwest hospital, according to Dr. Paul Stanley, Professor of Aeronautics, Astronautics and Engineering Sciences of Purdue University, 40 to 50 patients were shocked in a period of a few months because of a design error in an electromechanical dye injector. Assailing "poorly designed and shoddily built" equipment, Dr. Stanley said: "In some instances circuits have been lifted directly from published articles on the design of medical instruments without verifying the circuit's adequacy for the company's particular application."

However, the responsibility for preventing accidents does not fall entirely upon the manufacturers of equipment. Hospitals, too, must adopt higher standards of safety for electrical circuits in patients' rooms. The use of three pronged plugs and the installation of isolation transformers and alarms that automatically signal an open ground should be mandatory on the wards as well as in the operating rooms.

SEAT BELT INJURIES

This article points up the type of injury that may occur from the seat belt in a high speed auto accident. The patient with a solid viscus injury may present with shock and hypovolemia, but a hollow viscus injury may be

present in the patient and manifest itself in a more insidious manner, thus allowing precious hours to be lost. Three cases are presented. The authors are careful to point out that this injury is an acceptable risk to the alternate possibility of the rider becoming a hurtling free body following the impact, with its greater inherent danger.

MALLORY-WEISS SYNDROME

Hemorrhage from gastroesophageal lacerations caused by vomiting is known as the Mallory-Weiss syndrome. A review of the literature is presented and three new cases are reported. These lacerations may follow any event that brings about a marked increase in intra-abdominal pressure, such as vomiting, coughing, straining at stool, blunt external trauma, etc. It appears that this syndrome is frequently unrecognized in many patients with self-limited gastrointestinal bleeding. Only those cases requiring surgery or endoscopy have been recognized to date and reported as "rare" examples of Mallory-Weiss syndrome. This syndrome should be looked for in any patient with upper gastrointestinal bleeding and a history of vomiting or straining before bleeding.

SELECTIVE MANAGEMENT OF STAB WOUNDS OF THE ABDOMEN

A ten-year review of stab wounds of the abdomen treated at the Presbyterian-University of Pennsylvanian Medical Center was undertaken to ascertain whether it is justified for those physicians responsible for the care of these patients to be selective in deciding who needs immediate exploration and who may be safely observed.

The authors are concerned in their group of patients who were immediately operated upon, for only 32% proved to have injuries requiring repair. In their group of patients that were closely followed "conservatively,"[20] there were two significant injuries that should have had immediate repair; however, neither of these patients died. The authors are against a program of laparotomy for all patients with abdominal stab wounds.

Comment: More and more articles are mentioning selectivity in the care of patients with abdominal stab wounds. The two reasons given are the high incidence of no significant findings on routine exploration, and the fact that usually these patients present a higher than usual anesthesia risk. The practicing physician should note, however, that the authors stress very frequent detailed examinations in order to diagnose any developing problem. There is still considerable doubt as to the wisdom of this type of program.

THE FAT AMERICANS

People, Sir William Osler once observed, are apt to dig their graves with their own teeth. And Americans, say two London epidemiologists in *The*

Lancet, may burrow faster towards posterity than Englishmen.[1]

For after surveying cardiovascular symptoms, smoking habits, blood pressures, electrocardiograms, heights, weights, and skinfold thicknesses of 676 English Post Office workers and 625 similarly employed Americans, they close with this observation: ". . . American excess in ischemic heart-disease is most likely related to the adiposity of the American middle-aged male." Some of their facts on men aged 50 to 59 were these: 7.9 percent of the Americans had symptoms of angina against 4.6 percent of the English; 9.7 percent had symptoms of possible infarction versus 2.4 percent of the English; and Americans' cardiographs showed 7.9 percent with "probable ischemia" and 13.5 percent with "possible ischemia" while the English figures were 2.7 percent and 9.2 percent. Furthermore, those Americans from 40 to 59 had higher blood pressure (135/80 versus 130/78), stood taller (176.5 cm to 172.8 cm), weighed more (82.1 kg to 73.3 kg), and had thicker skinfolds at the triceps (19.0 mm to 8.3 mm) and under the scapula (21.6 mm to 14.6 mm). Because of these measurements and other figures, such as a 50 percent higher death rate from coronaries in the United States than in England and Wales, the epidemiologists indicated fatness as a likely contributing cause of sudden death in America.

One subject our two investigators did not go into is whether Americans eat more or exercise less. Though jogging has emerged as our "in" sport, weight reduction and exercise clubs have sprung up on both sides of the Continental Divide, and men pursue a ball with a liquid center across verdant fields, we still prefer to propel ourselves in the sitting position. The British maintain footpaths across their fields and meadows, but we surface our walking space with concrete to accommodate our cars as we speed home to our bountiful tables. We like our cars big and our concrete wide. It gives us the mobility, the comfort and the time we need to get to our spas, gymnasia, jogging grounds, and golf courses.

JUVENILE DIABETICS

Part of the literature on juvenile diabetes has been reviewed. The favorable immediate prognosis that can be offered today to the new diabetic child is contrasted to that of the pre-insulin era. Nonetheless, vascular complications occurring after relatively few years of the disease point to deficiencies in understanding and possibly to errors in treatment. Examination of current concepts about the etiology of these sequelae and their relationship to past control led to the conclusion that, whereas vascular pathology is probably inherent in the diabetic state, the degree of damage and the consequent loss of function could be modified to some degree at least by maintenance of good control. In this respect, the role of serum lipids and the dietary fat content were reviewed, but definitive conclusions seemed unwarranted. Oral hypoglycemic agents were shown to have little or no place in the treatment of juvenile diabetics. Continued careful observation of patients is needed to improve understanding and management of this disease.

SCREENING FOR CUSHING'S SYNDROME

What makes Cushing's syndrome tough to diagnose by laboratory tests? The confusion generated by the many types of tests available? The overlap between valves in patients with and without the syndrome? The careful control needed to give steroids to suppress adrenal function?

All are factors, but the big problem is collecting an accurate 24-hour sample of urine. Because of the human element, the collection of specimens tends to be poorly timed, or to be incompletely collected. These factors make it difficult to screen patients in offices or clinics, and they must be hospitalized to assure accurate tests.

Lately, though, a flurry of papers has appeared that indicate that plasma cortisol levels after a single dose of dexamethasone serve as well as more complex tests.[1-4] The principle is simple. In normal subjects, plasma cortisol is highest at 8 to 9 A.M. and lowest in the evening, whereas cortisols in patients with Cushing's syndrome do not vary much. Also patients with the syndrome, when given dexamethasone, do not usually decrease their cortisol level in the evening, as do normal subjects.

To test for Cushing's syndrome, then, measure the plasma cortisol in the morning and the evening (some consider this check on diurnal variation as optional[2]), give 1 mg of oral dexamethansone at 11 P.M. to midnight, and collect a blood sample at 8:00 A.M. the following morning for plasma cortisol. If the morning plasma cortisol level is suppressed (meaning levels less than 11 μg per 100 ml, 5 μg per 100 ml, 6 μg per 100 ml, 10 μg per 100 ml in the different series), Cushing's syndrome is ruled out.

The Sick In Soul

The sick in soul insist that it is humanity that is sick, and they are the surgeons to operate on it. They want to turn the world into a sickroom. And once they get humanity strapped to the operating table, they operate on it with an ax.—Eric Hoffer.

Special Article

Exercise—the Heart and the Doctor Athlete

A Nine-Year Survey

SERGIUS BRYNER, M.D.*
Palo Alto, California

EXERCISE AS a deterrent to myocardial infarction and death from myocardial infarction aroused little interest in this country at the start of this study, though Europeans were considerably more intrigued. In the last few years the idea has begun to incite dreams of longevity in the minds of a rapidly increasing number of doctors as well as laymen. At the 1967 American Heart Association meeting a substantial segment of papers bore on this question.

Now exercise enthusiasts and patients who have sustained myocardial infarctions, who have angina or positive exercise electrocardiographic abnormalities without angina, are filling our swimming pools, tennis courts, recreation centers, health clubs, ski slopes, mountain trails and the like and are making the bicycle industry prosperous.

The rationale and experimental basis for the belief that regularly-performed sustained-endurance exercise may act as a deterrent to ischemic heart disease has been previously studied with the following observations:

1. Obstruction or narrowing of a major coronary vessel is alleviated by a far richer collateral circulation in exercised than in sedentary subjects.
2. In such exercised subjects an additional coronary obstruction is less likely to be disastrous than in the slothful.
3. Increased fibrinolytic activity is stimulated by and persists for some time after exercise.
4. The potential for oxygen uptake is greater in athletically trained persons than in healthy nonathletic subjects due to the greater stroke volume and A-V oxygen differences in the former. (One might say that maximum oxygen consumption is a measure of the functional ability of the cardiovascular system.)
5. Mild hypertensives trained to become endurance athletes experience after training (for the same workload done before training) a drop in A-V oxygen difference, heart rate and oxygen consumption, and they are able to increase cardiac output to higher levels than before training.
6. Athletes are able to perform the same amount of work as nonathletes with less lactic-acid accumulation (oxygen debt).
7. Statistical studies from prospective programs such as the Framingham Project show that the risk of death or angina from coronary disease in the physically vigorous is approximately one third that in the sedentary population. However, these studies do not assess the reason for the sedentariness of some of the subjects nor the role of obesity.

*Palo Alto Medical Clinic.

The Present Study

A study was begun nine years ago with an annual questionnaire on 112 members of the Northwestern Medical Association. The study was not aimed at the effect of exercise on cholesterol levels, and not enough data on cholesterol was obtained to permit the collection of any significant data.

Period of Observations

Of the 112 members surveyed, 101 were followed through 1967 or died:

69 followed 9 years—1959 to 1967
23 followed 8 years—1960 to 1967

1 followed 7 years—1961 to 1967
8 died

Data from the other 11 were nevertheless sufficient to be used in the statistics tabulated.

Age Distribution

The participants were grouped by their age at the end of the study from Group I through VII as follows:

TABLE 1
Age Range of 112 Subjects in NWMA Coronary Disease Study 1959-67

Group No.	Age Range at End of Study	No. of Subjects
I	< 46	15
II	46 - 50	25
III	51 - 55	36
IV	56 - 60	11
V	61 - 65	17
VI	66 - 70	6
VII	71 - 75	2

Tobacco Consumption

During the course of the study there appeared to be an overall drop in tobacco use from about 41% to about 30% in the nine-year period, a decrease more marked in the older than in the younger age groups. Perhaps in the younger age group the philosophy "it can't happen to me" persists.

Dietary Habits

Roughly one third in each age group reported they followed a diet low in cholesterol and saturated fats.

Low in Saturated Fats and Cholesterol

TABLE 2
Use of Diets Low in Saturated Fats and Cholesterol by 112 NWMA Members 1959 - 1967

Group No.	Number Following Low Saturated Fat Low Cholesterol Diet: At Start Study	Number Following Low Saturated Fat Low Cholesterol Diet: At End Study	Number Abandoning Diet During Study	Number Adopting Diet During Study
I - 15	4	4	0	0
II - 25	7	8	0	1
III - 36	10	10	2	2
IV - 11	4	4	0	0
V - 17	5	6	0	0
VI - 6	2	2	0	0
VII - 2	0	0	0	0
Total	32	34	2	3

Weight Changes

The weight range of this group as a whole revealed no markedly over or underweight members. A few were slightly underweight. The following table shows the weight trend in the group without stating the degree of obesity, since for practical purposes the overweight was always of moderate degree.

TABLE 3
Incidence of Overweight in 112 NWMA Members 1959-1967

Group No.	Number Overweight at Start of Study	Number Overweight at End of Study
I - 15	4	5
II - 25	2	6
III - 36	9	11
IV - 11	0	5
V - 17	2	6
VI - 6	0	0
VII - 2	0	1
Total	17	34

These simple statistics show a rather clear-cut and striking trend in this small aging population of men, in that the incidence of obesity increased by 100%.

Morbidity

Very little nonfatal coronary artery or cardiovascular disease was found in this group.

Infarction

Nonfatal myocardial infarction occurred in one (a very moderate exerciser whose pattern would be classified as somewhere between light and moderate physical activity). This is therefore not a significant case in determining the incidence of ischemic heart disease in the vigorous exercise group.

Angina

Mild angina occurred in one subject who exercises moderately and who, as far as can be determined, no longer experiences the angina. Two other cases of chest pain are reported, both of doubtful significance. Angina with tobacco was reported by only one member, who later died of external causes. Another member reported one single episode of what he interpreted as angina when under great physical stress and threat to his safety.

Hypertension

Mild hypertension has been found in eight members. There has been some talk of exer-

cise as a preventative or cure for hypertension, but this group does not support that contention, since hypertension was not uncommon. It may be significant that all were mild hypertensives; but since four of these eight were classified as heavy or moderately heavy exercisers, a heavy exercise program does not appear to prevent hypertension.

Comments

Physiologists, who are involved in this kind of study, agree that for exercise to stimulate substantial and effective coronary and collateral growth it must be constant, consistent and of an endurance nature which taxes both circulation and ventilation and is accompanied by a sizeable and continuing increase in pulse and respiratory rates. Brief sporadic muscular challenges with no lasting effect on pulse and respiration other than that produced by repeated Valsalva maneuvers do not appear to be an appropriate type of exercise.

In spite of many attempts to acquire detailed data on exercise habits in the questionnaires there were too often answers such as "swim daily," "hunt, ski, fish, tennis and golf," "daily calisthenics," "frequent jogging" and the like, which were impossible to quantitate as to frequency, duration, speed, distance, intensity, etc.

Nevertheless, an assessment was made of each member's questionnaire as accurately as possible and exercise was classified into five categories: Light exercise, light-moderate exercise, moderate exercise, moderate-heavy exercise, and heavy exercise.

The "heavy" type of exercise (squash, tennis singles, very competitive tennis doubles for several sets, fast swimming over substantial distances of 400 yards or more, running, hill climbing, bicycle touring, exercycling against resistance to exhaustion, calisthenics which are long and vigorous, earth-moving type of yard work involving prolonged vigorous activity and the like) five or more times a week with infrequent lapses for illness, medical meetings and the like is challenging and should qualify as satisfactory endurance-type exercise. "Moderate-heavy" exercise may also qualify with some reservations and probably in many cases is also sufficiently vigorous to have a substantial effect on production of coronary collaterals in the presence of obstruction. In this category would be brisk, but not heavy endurance exercise done frequently and regularly or heavy type endurance exercise done less regularly than by those in the "heavy" category. In order for a member to qualify for the two heaviest categories of exercise at the end of the study it was necessary that he perform this type of exercise over a period of at least twelve months without any evidence of angina, syncope or other cardiac symptoms.

Since there is no scientific delineation of the exact amount and frequency of exercise required to rapidly develop generous collateral coronary circulation, one is forced to extrapolate in a rather crude way from animal experimentation and autopsy studies. Follow-up studies on the Vineberg procedures such as those reported by Gorlin do suggest that a substantial amount of coronary collateral circulation can be built up in the myocardium over a period of six months or less.

Some of the groups tabulated here are far too small to have any statistical significance. There has been a general shift away from "light" and toward "heavy" exercise in the group as a whole over the nine-year period of study, the biggest changes occurring away from the "light" and toward the "moderate-heavy" group.

Perhaps the most striking phenomenon is that in the groups studied, age seemed to have very little significance in exercise habits from decade to decade.

The Deaths

The deaths which occurred in this study had little bearing on the outcome of the survey. The ages at the time of death were 42, 43, 45, 50, 54, 55, 63 and 75. Two deaths were due to malignancy and two to external causes; four deaths were cardiac.

One myocardial infarction occurred at the age of 42 in a man who had been overweight for twelve years, who had had a normal EKG one year before, and who did not use tobacco. He had done heavy exercise in high school and college but light thereafter with only spurts of heavy activity (perhaps the worst kind of an exercise program).

Another myocardial infarction occurred at the age of 50 in a man who had smoked 20 cigarettes a day for 30 years and was slightly overweight. His exercise in high school was

heavy, but nil in college and light to moderate thereafter. He engaged in only moderate physical activity for several years prior to his death and was lost track of during the last two years before he died.

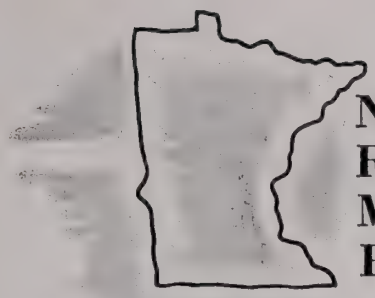
One death occurred in a man with hypertensive cardiovascular disease who had advanced heart disease from 1954, including a myocardial infarction, heart failure and severe peripheral vascular disease and who gamely continued to ski hard a few times each year, remaining largely sedentary for the rest of the time. This too would seem to be the worst possible exercise program for anyone — let alone an individual who was already a cardiac. This man did not smoke.

Another death occurred at age 75 in a man who did not smoke and who had mild nonanginal symptoms and electrocardiographic changes between 1964 and 1966, death occurring in 1966. Myocardial infarction was not proven, but death was almost certainly due to myocardial infarction or ventricular fibrillation resulting from ischemic heart disease. His exercise habits were moderate but very regular, consisting of three sets of tennis two or three times a week for six months of the year, swimming two to three times a week three months a year, and skiing when he could. We do not know how hard he swam, but we classify this program as moderate because the level of activity was doubtless not very high and also because it probably was neither year-round nor daily. Nevertheless it is of great interest that this man was able to carry on this exercise program after the occurrence of syncope and electrocardiographic change without developing any angina. The fact that syncope was his only symptom prior to death and that the final episode was also a syncopal attack tempts one to speculate whether the exercise program was vigorous enough to develop sufficient collateral circulation to prevent myocardial infarction and angina but not to prevent a fatal arrythmia due to a partially ischemic area of the myocardium.

At the end of the study 41% of the subjects were in the 2 heaviest exercise groups and presented no adequate evidence of ischemic heart disease except for one in the "moderate-heavy" category who while being symptom free had a "positive treadmill test" about which no further details are proven.

Conclusions

While not offering conclusive proof for the value of frequent, challenging, endurance-type exercise as a deterrent to ischemic heart disease this study gives encouragement and support to the possibility that this type of exercise when properly performed may be of value. Larger prospective studies will have to be completed before a conclusive answer to this question can be obtained; and, ideally, angiographic studies should be available but are not likely to be in the foreseeable future.



Perhaps the "heavy" group should be studied in other perspectives. Are they a compulsive, unhappy group? Are they as productive as they should be? Are they more neurotic than the less disciplined members of society? Being one of the group myself I have no hesitation in casting these aspersions. It would be of significant interest and value to have a psychological test study of this group of "heavy" and "moderate-heavy" members.

Whether or not the very low incidence of tobacco usage in these groups plays a major part in their continuing good cardiac health remains also for the moment unanswered.

Your Health—Mr. President

It is interesting to note that of the first thirty Presidents the average age at death for the first ten, up to and including John Tyler who died in 1862, is 77.4 years; for the second ten, from Polk to Garfield, 63.7 years; and for the Presidents from Arthur on, 63.1 years. Of the first group, John Adams lived to the age of ninety, three others were in their eighties when they died, and only two, Washington and William Henry Harrison, were under seventy at the time of their death. And this in spite of the epidemics of infectious diseases, the lack of sanitation, and the primitive state of medicine during most of that era! How can one explain the fact that despite all the advances of modern medicine, the Presidents of the twentieth century pre-decease their early predecessors by an average of more than fourteen years?*

*Karl C. Wold, M.D.: Mr. President—How Is Your Health?

NORTHLANDS REGIONAL MEDICAL PROGRAM

REGIONAL PROGRAM FOR HEART DISEASE, CANCER AND STROKE

A New Medical Information System
The Dial-Access Medical Library

1. *A new Information Resource for Minnesota Physicians*

   All physicians in Minnesota will soon have immediate telephone access to a library of authoritative magnetic tape abstracts of a wide variety of medical subjects.

   Northlands Regional Medical Program will join Wisconsin Regional Medical Program to expand Wisconsin's Dial-Access Medical Library and make it available by toll-free telephone transmission to all physicians in both states. The Wisconsin program was developed under the leadership of Dr. Thomas Meyer, Director of the Department of Post-Graduate Education of the University of Wisconsin College of Medicine, and has operated successfully since 1966. Under the new cooperative arrangement Minnesota physicians will participate by producing new tapes to equal the contributions of Wisconsin physicians.

   All physicians in Minnesota will receive a copy of the catalogue and complete instructions by mail. Display units with extra catalogues will be placed in every hospital.

2. *The Medical Library* is a library of five minute magnetic tape abstracts of single topic medical subjects. Each tape is prepared by an expert on the subject, who is identified in the catalog and at the end of the recorded abstract. All recordings are updated annually or oftener so that information is always current.

   The Wisconsin Library now contains 225 single concept tapes. Minnesota Regional Medical Program joins Wisconsin Regional Medical Program to progressively enlarge the library and make it accessible to all physicians in both states.

3. *Dial-Access*

   In-Wats telephone line rental makes it possible for any physician to call the library, toll free, from any telephone, at any time day or night, 365 days a year.

   The library is operated by personnel of the University of Wisconsin Emergency Pharmacy, which is staffed 24 hours a day.

   The physician simply dials the Wats line number, identifies himself, requests his choice of tapes and then listens as the tape is played for him.

   In order to limit use to physicians and to provide a means for evalua-

tion of the efficacy of the program, each caller is asked to identify himself. Service is refused to non-physicians.

4. *Further Telephone Consultation*

   Each tape author has agreed to accept personal calls from physicians for additional consultation whenever anyone desires. (This cannot be toll-free, however.) The additional service to physicians also permits reception of ideas for improvements or additions to the library.

5. *Evaluation*

   The method permits the following evaluations:

   a. Total number of requests, by hour, day, week and month.
   b. Number of requests for each tape in library.
   c. Random sample opinions from physicians using the service (by post-card questionnaire). Such feed-back permits constant up-grading of the library.

6. *Potential Expansion to Para-medical Disciplines*

   The Wisconsin Regional Medical Program is in the process of developing an analogous Nursing Library. Similar programs could easily be developed for other paramedical disciplines.

7. *Future Potential*

   If this system can be expanded to cover the entire field of medicine, it will then constitute a medical encyclopedia which is always up to date and always accessible from any telephone.

   The magnetic tape library can be replaced by a computer data bank when size and need dictate. Printed copy display on cathode-ray tube units with attachments for production of instant hard copy is also possible. Automated cataloguing, indexing, and searching programs can provide amazingly rapid retrieval of desired information from an enormous bank of computer stored information.

This is the first program instituted by Northlands Regional Medical Program to help make the latest in medical care knowledge constantly available to all practicing physicians. We hope and trust that Minnesota physicians will use the system and help us to make appropriate modifications and additions.

Winston R. Miller, M.D., F.A.C.P.
Program Director

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures highlighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

The man who becomes puffed up is ready to fall down.—Forbes Epigrams

Meetings and Announcements

JULY

Summer Camp for Diabetic Children, July 14 through August 4, at Holiday Home, Lake Geneva, Wisconsin. Applications may be obtained from: Diabetes Association, 620 North Michigan Avenue, Chicago.

Postgraduate Course, Ophthalmology, The Stanley Hotel, Estes Park, Colorado, July 8-11. Contact: University of Colorado School of Medicine, Denver.

Air Pollution Medical Research Conference (Sponsors: Denver Medical Society, Colorado Medical Society, American Thoracic Society, American College of Chest Physicians, Colorado State Dept. of Public Health, U.S. Public Health Service, and American Medical Association), Denver-Hilton Hotel, Denver, July 22-24. Info.: AMA Department of Environmental Health, 535 N. Deaborn St., Chicago.

Tenth Annual Methodist Hospital Symposium

The tenth annual symposium, sponsored by the Methodist Hospital medical staff, will be held on Saturday, September 14, 1968, in the Methodist Hospital auditorium.

The subject for this coming year's symposium will be on current concepts and treatment of "shock."

The Minnesota Academy of General Practice has approved this symposium for six prescribed hours of credit.

There is no registration fee for the scientific sessions or the noon luncheon. All physicians are most cordially invited to attend. For additional information please contact Mrs. Audrey Engstrom, medical staff secretary, 929-1313.

Sixth National Cancer Conference

Conference will be held September 18-20 in Denver, Colorado. For full information contact: American Cancer Society, 3702 E. Lake Street, Minneapolis. Phone 722-6614. Subjects to be discussed are cancer of the female pelvis, gastrointestinal tract, skin, neck and head, and lung. Also to be discussed are skeletal tumors, soft part tumors and basic problems and advances in cancer chemotherapy and hormone therapy.

Radiological Technologists Meeting

Minnesota Society of Radiological Technologists will meet October 11 and 12 at the Kahler Hotel in Rochester. Contact: James Powers, R.T., Mayo Clinic, Rochester.

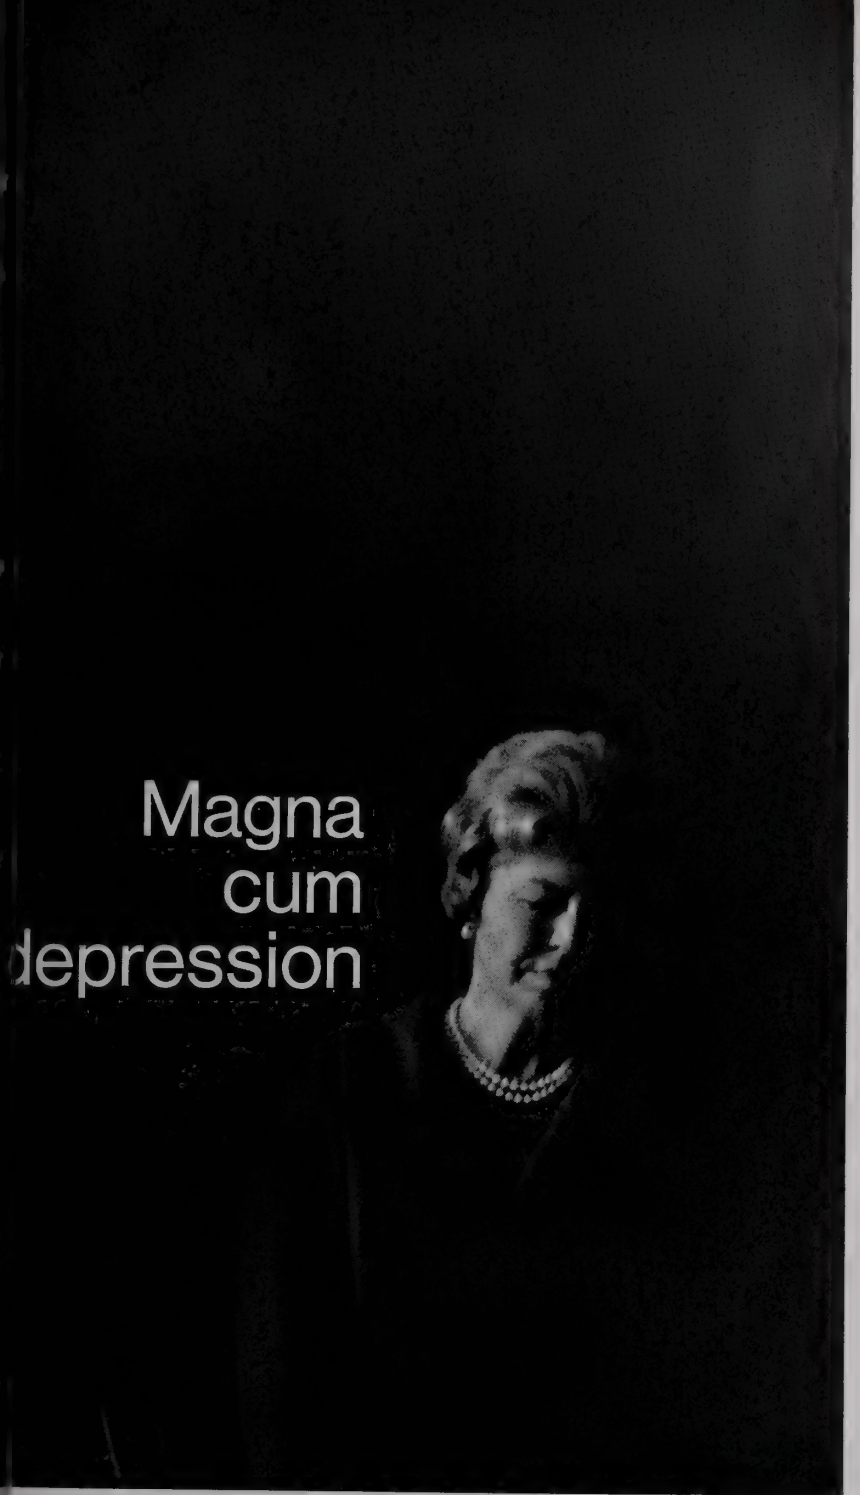
The Minnesota Thoracic Society and the Minnesota Respiratory Health Association announce a second award contest for medical students, interns and resident physicians in Minnesota.

(A) An award of $200.00 is offered for the best paper submitted by a senior medical student or intern on some aspect of respiratory disease, preferably based upon laboratory or clinical investigation.

(B) An award of $300.00 is offered for the best paper submitted by a resident physician based upon clinical or laboratory investigation in the area of respiratory disease.

Further information may be obtained from the Secretary. Entries should be submitted by September 1, 1968 to: David E. Dines, M.D., Secretary, Minnesota Thoracic Society, Mayo Clinic, Rochester, Minnesota.

Minnesota Surgical Society Essay Prize



A prize of $500 will be given for the best paper on a surgical subject submitted by a medical student, intern or resident. Papers directed to surgical research and papers on clinical topics are acceptable. Research subjects presented for consideration should be those which clearly have clinical application. The winner will be asked to present his paper at the Fall meeting. Granting of the award is contingent upon the willingness of the author(s) to submit the manuscript for publication in Minnesota Medicine.

Deadline for submission of manuscripts is August 1st, 1968. These should be sent to John F. Perry, Jr., M.D., at the Saint Paul-Ramsey Hospital, 640 Jackson Street, Saint Paul, Minnesota. It is hoped that members of the Society throughout the state will bring this to the attention of house officers and students and encourage them to submit papers.

Tofrānil®, imipramine hydrochloride

Indications: Tofrānil is recommended for the treatment of depressive states of diverse psychopathology.
Contraindications: The concomitant use of this agent and monoamine oxidase inhibiting (M.A.O.I.) compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur. Potentiation of adverse effects can be serious or even fatal. An interval of at least 7 days after M.A.O.I. therapy has been discontinued should be allowed before this drug may be substituted. Initial dosage should be low, increases should be gradual, and the patient's progress should be carefully observed.
Warning: Clinical reports have suggested that there may be a risk of teratogenesis associated with the use of this compound during the first trimester of pregnancy. Unless, in the opinion of the prescribing physician, the potential benefits outweigh the possible risks, it should not be used during the first trimester of pregnancy. Cardiovascular complications, including myocardial infarction and arrhythmias, have occasionally occurred in susceptible individuals. Patients with cardiovascular disease should be given the drug only under careful observation and in low dosage.
Precautions: Since suicide is always a possibility in severely depressed patients and one which may persist until significant remission occurs, such patients should be carefully supervised during early treatment. Some severely depressed patients may also require hospitalization and/or concomitant electroconvulsive therapy. Because of its anticholinergic effect, caution should be observed in prescribing the drug for patients with increased intraocular pressure.
In rare instances, transient cardiac arrhythmias have occurred in hyperthyroid patients and in patients receiving thyroid medication when this compound was added to the regimen.
Imipramine may block the pharmacologic activity of guanethidine and other related adrenergic neuron-blocking agents.
The drug is not recommended at the present time in patients under 12 yea of age.
Adverse Reactions: Dryness of the mouth, tachycardia, constipation, disturbances of accommodation, sweating, dizziness, weight gain, urinary frequency or retention, nausea and vomiting, peripheral neuritis, mild parkinson-like syndrome, tremors, rare cases of falling in elderly patients, confusional states (with such symptoms as hallucinations and disorientation), activation of psychosis schizophrenics and agitation (including hypomanic and manic episodes) which may require dosage reduction

For him, commencement.

For his mother, the beginning of his career may seem the end of hers. The end of feeling needed and useful. The beginning, perhaps, of a pathological depression.

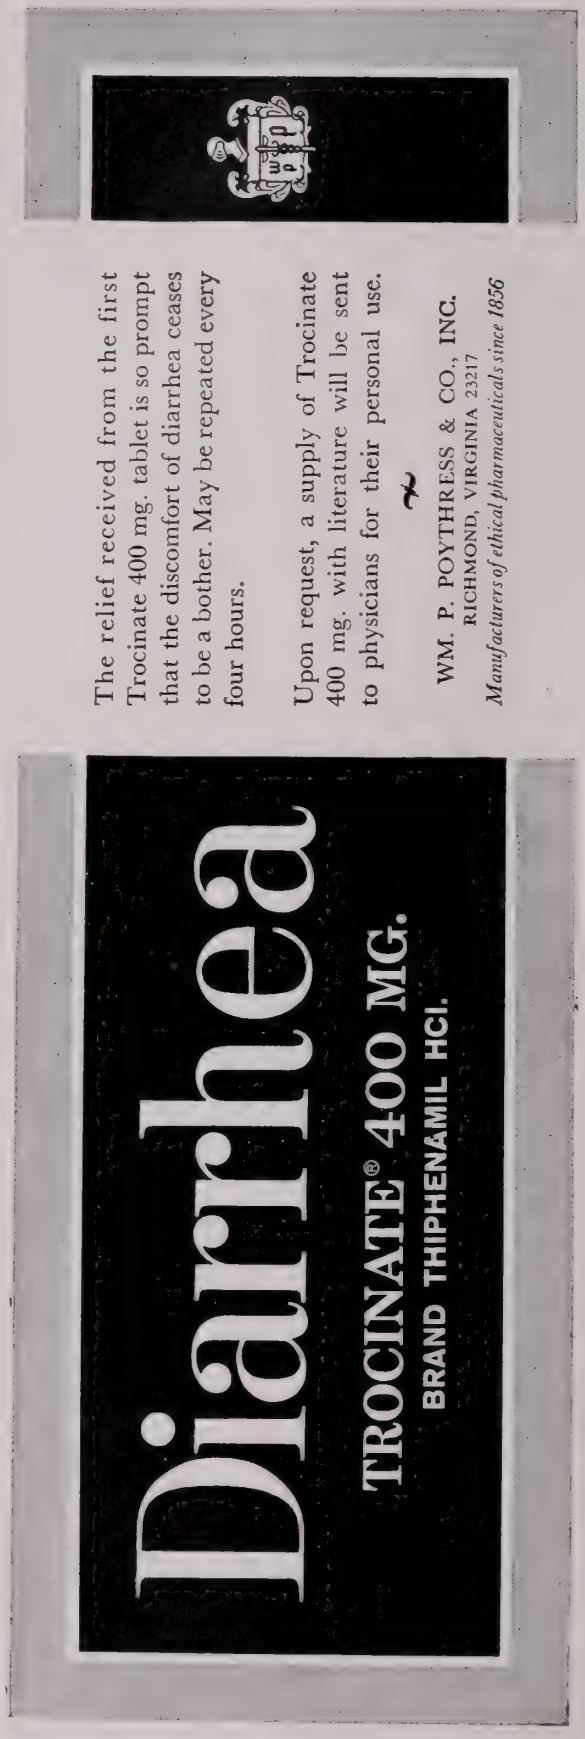
Tofrānil can often relieve the symptoms of her depression. If it can relieve her mental anguish, you may be able to help her graduate into a new and fruitful life of her own.

Tofrānil could be her commencement, too.

Tofrānil® Geigy
imipramine hydrochloride

in depression

The use of Tofrānil in patients receiving M.A.O.I.'s is contraindicated.



In patients with cardiovascular disease, hyperthyroidism or increased intraocular pressure; in those receiving anticholinergics (including antiparkinsonism agents), thyroid medication or adrenergic neuron-blocking antihypertensive agents; and in those in the first trimester of pregnancy, the precautions discussed in the Prescribing Information should be carefully observed. Although toxic reactions severe enough to require discontinuation of Tofrānil are uncommon, please refer to the Prescribing Information for a description of such instances when discontinuation may be necessary.

d/or addition of a tranquilizer or
mporary discontinuation of the drug,
ileptiform seizures, orthostatic
potension and substantial blood
essure fall in hypertensive patients,
rpura, transient jaundice, bone mar-
w depression including agranulocy-
sis, sensitization and skin rash
cluding photosensitization, eosino-
ilia, and mild withdrawal symptoms
sudden discontinuation after pro-
nged treatment with high doses.
casional hormonal effects (im-
tence, decreased libido, and estro-
nic effects) may be observed.
ropine-like effects may be more
onounced (e.g. paralytic ileus) in
sceptible patients and in those
ing anticholinergic agents (includ-
g antiparkinsonism drugs).
utpatient Adult Dosage: Initially,
mg. daily, increased, if necessary,
150 or 200 mg. Maintenance dosage
ay be lower, 50 to 150 mg. daily, if
ssible.

Geriatric and Adolescent Dosage: Initially, 30 or 40 mg. daily, which may be increased according to response and tolerance. It is usually unnecessary to exceed 100 mg. daily.
A lag in therapeutic response, lasting from a few days to a few weeks, should be expected. When dosage recommendations are already being followed, increasing the dosage does not normally shorten this latency period and may increase the incidence of adverse reactions.
Availability: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg. for geriatric and adolescent use; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration.

Hunting, 9-hole golf course, swimming pool. Salary open and full partnership as soon as desired. Write: Minnesota Medicine—405, 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER urgently needed to join two established General Practitioners in a thriving clinic practice, thirty miles from Minneapolis-St. Paul. Third man is leaving for residency. State military status and references. Early partnership would be preferable. Write: MINNESOTA MEDICINE-406, 375 Jackson, St. Paul 55101.

DOCTOR WANTED in Fairfax Minnesota. Clinic building available. Present doctor leaving. This is an excellent opportunity. Please contact Dr. Glenn Nelson or Leo Keller at Fairfax.

WANTED BY TWO INTERNISTS—a Board Eligible or Board Certified Internist to practice in the Twin City area. Excellent opportunity and early partnership. Write: MINNESOTA MEDICINE-407, 375 Jackson, St. Paul, 55101.

WANTED: Board certified or eligible general surgeon to join established 3 man group, building large, new clinic in Jonathan-Chaska, newest "planned city" located just outside Minneapolis. Attractive opportunity with partnership after one year. Outstanding hospital. Write MINNESOTA MEDICINE-408, 375 Jackson, St. Paul 55101.

THE WEST MEDICAL CLINIC has an opening for a General Practice Physician, on October 1, 1968. This is a five man group that conducts a practice near downtown St. Paul and also, has the Airport Medical Clinic at Wold Chamberlain Field, Twin City International Airport. Both clinics have full laboratory and x-ray services with technologists covering both fields.

The Airport Medical Clinic does industrial, occupational and Aviation medicine. FAA examinations are conducted at both clinics.

The clinic located near downtown St. Paul has a practice limited principally to internal medicine, pediatrics, as well as occupational and industrial medicine. There is only a limited practice of obstetrics and no surgery.

Salary is open and opportunity for partnership is available. Write: West Medical Clinic, 539 W. Seventh Street, St. Paul, Minnesota 55102. Phone: Area Code 612-227-9341.

LONG LAKE needs doctor. Professional bldg. for sale or rent. Has waiting room with reception counter, two toilets, lab-darkroom, large X-ray room plus five other rooms. Picker 100-100 century now installed. Sublease income. Fifteen miles west of Minneapolis. Wide open for doctor. Village Real Estate, Long Lake, Minnesota. A.C. 612-473-9630.

WANTED—Board Certified or eligible Internist to join two established Internists in medium sized, college community in Minnesota lake country. New clinic facilities. Salary negotiable. Write MINNESOTA MEDICINE 409, 375 Jackson, St. Paul 55101.

PHYSICIAN NEEDED IMMEDIATELY—Attractive opportunity for general practitioner in rapidly expanding all new community of Silver Bay, Minnesota, a growing world's first large scale taconite center. Area population 6,000 on beautiful Lake Superior, gateway to Northern Minnesota's infinite vacation variety land. The area's natural resources for year round sports and recreation are unexcelled—good hunting, skiing, golfing—near metropolitan area of 125,000 population. Attractive financial arrangements and liberal fringe benefits for physician to take care of medical industrial needs of Reserve Mining Company in addition to private practice. Present doctor near retirement age presents wonderful opportunity for physician to relocate or young physician wishing to establish rewarding practice; excellent monetary potential proportionate to ability and desire to work. No investment necessary. Submit resume of education and experience in confidence to John A. Smrekar, Reserve Mining Company, Silver Bay, Minnesota 55614

DESIRE TO GIVE away a general surgery practice which should immediately provide a versatile surgeon with 200 majors annually and unlimited ceiling. Will provide modern office facilities in a ten-year-old clinic building and guarantee a minimum income with no strings attached. Should be board qualified and under forty-five. Excellent hospital facilities with resident anesthesiologist and pathologist. Reason:—desire to limit my practice to Urology. Write or call O. K. Behr, M.D., 407 North Broadway, Crookston, Minnesota—Area Code 218-281-3210.

Radiology

Resident's Day Research Symposium of the Department of Radiology of the University of Minnesota, Minneapolis, was held May 16. The following medical fellow specialists presented papers describing their research projects:

Dr. James Thomson: "Combination of cytosing arabinoside with x-radiation in the therapy of an experimental mouse brain tumor."

Dr. Robert E. Anderson: "Dosimetry of the North American Field for radiotherapy of Hodgkin's disease using cobalt 60."

Dr. Robert Jeffrey: "Detection of left-to-right cardiac shunts using Freon as an indicator."

Dr. Virgil T. Fallon and Carl Jessen: "Modification of swine skin radiation reaction by topical steroid therapy."

Dr. D. J. Purdie: "Comparison of isotopic and radiographic techniques for renal localization."

Dr. Harry Baltaxe: "Coronary angiography in hypercholesterolemic patients."

Dr. Robert Carlin: "Cardiac papillary muscle dysfunction studied radiographically."

Dr. Eugene Binet: "Radiographic and scintiphotographic studies of cerebral vascular lesions."

Minnesota Medicine at a Glance

Marinesco-Sjögren Syndrome—*Alter and Kennedy* Page 901

A rare syndrome manifested primarily by incoordination, cataracts, and mental and physical retardation is thoroughly analyzed both by case presentation as well as critical analysis of the literature. A reader may gain a comprehensive understanding of the various criteria necessary for diagnosing this condition.

Placental Localization—*Loken et al.* Page 907

An interesting initial study on the localization of the placenta by the use of technetium^{99m}-labelled albumin in 51 patients. There was a 2% error when checked by digital examination at the time of delivery. The technique appears to be of no risk to the fetus and may be of help in diagnosing placenta previa.

Mediastinoscopic Diagnosis of Sarcoidosis—*Johnsen et al.* Page 915

The authors briefly outline the technique of mediastinoscopy and the application of this procedure in certain types of intrathoracic disease. The procedure appears safe in that minimal morbidity and no mortality resulted in this series of 100 patients.

The Grey, Creeping Death

When we examine in retrospect the long line of artists, poets, thinkers and musicians whom today we admire and love, we find many of them living and creating under the shadow of this malignant disease (syphilis), under its curse and its blessing.

The ordinary man might be inclined to close his eyes and turn away in distress to avoid polluting the pure image of those great minds, but the doctor is fascinated by them. For him syphilis is no moral criterion; it does not detract from the greatness of those men. They ran blindly into danger, they were ennobled and then destroyed. They paid the price with their blood and their destruction. One of the most distressing cases is that of Nietzsche. A single, involuntary error, committed under the all-powerful urge of sex, envenomed his body with the dangerous poison that fanned the flames of his genius. In 1889 he entered the Vienna Lunatic Asylum, a helpless wreck, living in a twilight for eleven years until his death. The same fate was suffered by Hugo Wolf, who within a few months composed two or three hundred superlative lieder, generously expending his genius which still enchants us today, until, helpless and oafish, he lay chained to his bed in a padded room. Donizetti, deMaupassant, Baudelaire and many others who produced works of great genius were embraced by the muse but also by syphilis. "Praise be their misfortune, for they have wrested the highest that is humanly possible from their disease." (Romain Rolland.)*

when he needs an antibiotic
he may be a candidate for

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

b.i.d.

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropri measures should be taken.

In infants, increased intracranial pressure with bulging fontanels h been observed. All signs and symptoms have disappeared rapidly up cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, di rhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculop ular and erythematous rashes; a rare case of exfoliative dermatitis h been reported. Photosensitivity; onycholysis and discoloration of nails (rare). Kidney—rise in BUN, apparently dose related. Transi increase in urinary output, sometimes accompanied by thirst (rar Hypersensitivity reactions—urticaria, angioneurotic edema, anaphyla Teeth—dental staining (yellow-brown) in children of mothers given t drug during the latter half of pregnancy, and in children given the d during the neonatal period, infancy and early childhood. Enamel hy plasia has been seen in a few children. If adverse reaction or idios crasy occurs, discontinue medication and institute appropriate thera

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should given 1 hour before or 2 hours after meals, since absorption is impai by the concomitant administration of high calcium content drugs, fo and some dairy products. Treatment of streptococcal infections sho continue for 10 days, even though symptoms have subsided.

LEDERLE LABORATORIES, A Division of American Cyanamid Comp
Pearl River, New York

■ to help restore and stabilize the intestinal flora

■ for fever blisters and canker sores of herpetic origin

LACTINEX contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

First introduced to help restore the flora of the intestinal tract in infants and adults,[1, 2, 3, 4] LACTINEX has also been shown to be useful in the treatment of fever blisters and canker sores of herpetic origin.[5, 6, 7, 8]

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

Today's physician sees more on NCME TV...

BETTMANN ARCHIVE

The first nationwide medical television service, NCME—The Network for Continuing Medical Education—brings you visually the important achievements of leading medical authorities. By means of closed-circuit television, this independent network provides your hospital or medical school with a complete videotape service that helps shorten the gap between new medical knowledge and its availability for clinical or teaching purposes.

NCME
The Network for Continuing Medical Education

NCME TV Offers These Practical Benefits:

☐ Every two weeks a new 60-minute videotape dealing with three separate medical subjects is sent to participating institutions.

☐ Content and format of NCME telecasts fulfill criteria for postgraduate medical education, permitting American Academy of General Practice course credits under specified conditions.

☐ To help your institution make effective use of closed-circuit television, NCME offers a wide range of services and utilization aids, including: Technical consultation in setting up a closed-circuit system; advance program information on the contents of each telecast; display units to help publicize programs; expense-paid seminars to improve utilization of medical television.

☐ NCME programs are brief and may be shown as often as desired; you can view the telecasts at times that are most convenient, without disrupting your normal schedule.

☐ Frequently NCME makes available published papers related to subjects presented on closed-circuit television.

A recent NCME hospital telecast presented Philip N. Sawyer, M.D., Professor of Surgery and Head of the Vascular Surgical Service at Downstate Medical Center, Brooklyn, N.Y., in a demonstration and evaluation of "Gas Endarterectomy."

In this program, Dr. Sawyer performs the operation on a patient with gross occlusion of the right iliac, femoral and popliteal arteries.

In Dr. Sawyer's view, gas endarterectomy has several advantages over mechanical methods: the operation can be completed faster, causes less damage to the arteries and offers a more successful outcome.

NCME is an independent network supported by Roche Laboratories to increase the use of closed-circuit TV for medical education under direct hospital and school control.

If your hospital or school does not participate in the biweekly NCME program, information on the cost-free service may be obtained by writing to NCME, 342 Madison Avenue New York, N.Y. 10017

GENERAL INFORMATION

Authors

Send manuscripts, subscriptions and communications for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101. Telephone 222-6366.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers

Q. How much does the **anticostive*** **hematinic** cost?

A. No more than costive hematinics cost!

The anticostive hematinic is

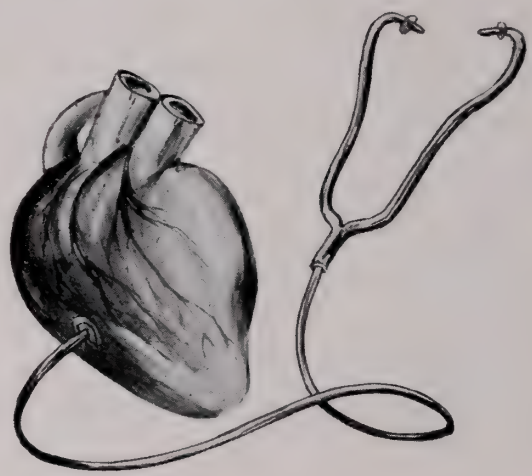
PERITINIC®

Hematinic with Vitamins and Fecal Softener

A tablet-a-day provides:

● Elemental Iron (as Ferrous Fumarate)	100 mg
● Dioctyl Sodium Sulfosuccinate (to counteract constipating effect of iron)	100 mg
Vitamin B_1	7.5 mg
Vitamin B_2	7.5 mg
Vitamin B_6	7.5 mg
Vitamin B_{12}	50 mcgm
Vitamin C	200 mg
Niacinamide	30 mg
Folic Acid	0.05 mg
Pantothenic Acid	15 mg

Bottles of 60



*

anticostive, *adj.* (*anti* opposed to + *costive* causing constipation.) Against constipation. Now isn't that a good idea in an iron-containing hematinic?

Just one tablet at bedtime • Prevents painful night leg cramps • Permits restful sleep

How many of your patients stamp their feet at night and lose sleep because of painful leg cramps? Unless prompted, they usually fail to report this distressing condition and suffer needlessly.

One tablet of QUINAMM at bedtime usually controls distressing night cramps and permits restful sleep with the initial dose.

Prescribing information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Side Effects/Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

President's Letter

IN THE INTRODUCTION to the "Practice of Physic" (1798), Richard Temple observes that "The publications of ingenious and observing men, who have paid particular attention to particular diseases, have also furnished us with a happier and more successful mode of treating them."

Such men from the Cleveland Clinic we welcome to these pages of Minnesota Medicine. Long renowned for distinguished medical reporting, contributors from this organization are no strangers to this reading audience. When we have digested and assimilated what they have brought to us, we can perhaps agree with thoughts expressed by Friend in his "History of Physic" (Volume 1). —"Every physician will make, and ought to make, observations from his own experience; but he will be able to make a better judgement and juster observation by comparing what he reads and what he sees together."

The Minnesota State Medical Association, through the medium of its journal, is proud to present this Cleveland Clinic issue.

The Fat Embolism Syndrome

CHARLES M. EVARTS, M.D.*
Cleveland, Ohio

FOR MORE than a century the fat embolism syndrome has stimulated many clinical and experimental studies.[1-4] Its relationship to skeletal and soft tissue injury has been recognized and several cases have been reported.[5] Nontraumatic conditions such as diabetes, burns, blood transfusions,[6] severe infections, poisoning, sickle cell disease,[7] cardiopulmonary bypass[8] and renal homotransplantation[9] may also result in the fat embolism syndrome. Its incidence remains high both on the battlefield and in civilian life. The seriousness of this complication of trauma is generally not appreciated. Controversy continues over the source of the embolic fat. Systemic fat embolism produces a clinical syndrome with characteristic clinical findings and pertinent laboratory test results.[10] Recent advances in the recognition and treatment of fat embolism have contributed to a decrease in morbidity and mortality.

Pathogenesis

For many years the source of the embolic fat was assumed to be intravasation of the fat into the vascular channels at the fracture site. Bone, because of its high fat content, vascularity, and rigidity, provided the ideal setting whereby increased interstitial pressure could force the free fat into vascular channels. In support of this mechanical theory, bone marrow fragments have been found within the lungs.[11]

The physiochemical theory postulates an alteration of the normal plasma colloidal dispersion of chylomicrons, which occurs after trauma, with coalescence of the chylomicrons into larger fat droplets.[12] After trauma the lipid-mobilizing hormone is activated and blood lipid concentrations increase, resulting in a change in the physical state of the blood lipids.[13] Injection of radioiodine (I^{131}) labeled triolein at the ends of fracture sites in experimental animals revealed a slow rate of absorption, demonstrating that the fat absorbed from

*Chief of Orthopedic Residency Education Program and Head, Department of Anatomy, The Cleveland Clinic Foundation, Cleveland, Ohio.

Fig. 1—Common sites of petechial rash.

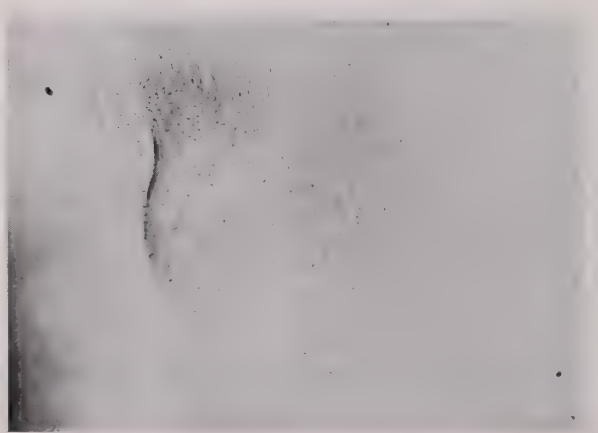

Fig. 2—Petechial rash in axilla.

the site of injury is not the only source of embolic fat.[14]

In the last few years, considerable attention has been directed to the rheology* of blood in the microvasculature (vessels with an internal diameter of less than 100μ). The fluidity of blood is altered by tissue injury, and microcirculatory changes occur. The flow patterns and flow rates of blood cells are notably altered. The changes after tissue injury can be summarized as follows:[15] (1) immediately after injury, aggregation of platelets and chylomicrons occurs, with the formation of white masses; (2) within a few hours after injury, aggregation of erythrocytes occurs; (3) a decrease in the flow rate of erythrocytes occurs in the postcapillary venules and sinusoids. Occlusion or sludging of the erythrocytes may occur. Poor tissue oxygen perfusion with hypoxia or anoxia is the obvious end result.

Therefore, the posttraumatic changes that occur in the microvasculature, in combination with the presence of circulating fat droplets (as a result of alteration of normal lipid stability) provide the physiologic basis for the fat embolism syndrome.

Clinical Manifestations

The fat embolism syndrome is most common in the second and third decades of life, and in the sixth and seventh decades when fractures of the hips are frequent. Ninety percent of the patients demonstrate symptoms within 48 hours after injury, but this time interval may vary from a few hours to four days. An initial latent period without symptoms may occur (Table 1).

Fulminating cases after severe multiple injuries are seldom recognized. Mild cases are frequent but often are not diagnosed. The clinician must have a high index of suspicion to make the diagnosis of the fat embolism syndrome, though its characteristics are specific enough to allow early recognition. Symptoms often begin suddenly and are a manifestation of tissue hypoxia and/or anoxia (signs are dyspnea, cyanosis, disorientation, and delirium). Restlessness and obstreperous be-

*See Test Your Word Score Page 1083.

havior are common. The clinical signs associated with the fat embolism syndrome are a rise in temperature to as high as 103F; tachycardia with a pulse rate of 140; a respiratory rate of 30 to 34. The neurologic examination may demonstrate a changing picture, with occasional extensor posturing and decerbate rigidity. On the second or third day after injury, petechiae often are seen across the root of the neck, in the axillae, and in the conjunctivas (Figure 1). The petechial rash is present for only a few hours and fades rapidly (Figure 2).

Laboratory Findings

Laboratory studies are helpful in the diagnosis of the fat embolism syndrome (Table 2). In approximately 50 percent of the patients, free fat is demonstrated in the urine within the first three days after onset of the syndrome. The urine supernatant fluid must be stained with freshly filtered Sudan III stain and examined for free fat droplets. An unexplained decrease in the blood hemoglobin content often occurs in the early stages of the syndrome. As the fat in the urine decreases, the serum lipase content increases in about 50 percent of the patients. When the diagnosis is suspected, serial examinations for fat in the urine, and the determination of serum lipase content should be started.[16] A roentgenogram of the chest may demonstrate the "snowstorm appearance" that is associated with the fat embolism syndrome (Figure 3). A skin biopsy of a petechial lesion may reveal the presence of intravascular fat. Differential diagnosis includes evaluation of possible acute occult blood loss, drug idiosyncrasies, oversedation, craniocerebral injury, and delirium tremens.

Treatment

Certain general measures should be employed in the treatment of fat embolism. The patient's airway must be maintained; shock must be treated; fluids must be administered; unnecessary transportation must be avoided.

The respiratory failure associated with fat embolism is best treated by mechanically assisting respiration and by the intravenous administration of corticosteroids (100 mg every six to eight hours). Oxygen decreases the tissue hypoxia, and should be given immediately after the diagnosis of fat embolism is suspected. Specific treatment should be directed at lowering the plasma lipid concentrations, preventing platelet aggregation, and improving microcirculatory flow.

Heparin

Injection of heparin, which has specific chylolytic action, will facilitate the passage of chylomicrons into tissues. Heparin activates the lipoprotein lipase and promotes the hydrolysis of the chylomicron to unesterified fatty acid. The fatty acids in solution in the plasma are bound by albumin. The lipoprotein spectrum of the plasma is also altered by heparin, and a change in the physical state of the blood lipids occurs. The anticoagulant action of heparin prevents agglutination of the platelets and improves microcirculatory flow. Small intravenous injections of from 10 to 50 mg of heparin every six to eight hours will achieve a chlolytic effect without the risk of hemorrhage. Heparin used in less than anticoagulant dosage has been beneficial in the treatment of the fat embolism syndrome.[17]

Dextran

Low molecular weight dextran (mean molecular weight of 40,000) is a useful addition to the treatment of the fat embolism syndrome.

TABLE 1
Clinical Manifestations of Fat Embolism Syndrome

Symptoms
1. Dyspnea
2. Restlessness
3. Confusion
Signs
1. Temperature elevation to 103F
2. Tachycardia—rates to 140 or higher
3. Tachycardia—rates to 30 or higher
4. Deterioration in the mental state
5. Changing neurologic reactions
6. Petechiae across the chest, in the axillae, root of the neck, or conjunctivas

TABLE 2
Laboratory Studies, Aids to Diagnosis of Fat Embolism Syndrome

1. Lipuria
2. Serum lipase content (elevation)
3. Blood hemoglobin content (unexplained decrease)
4. Serial roentgenograms of the chest
5. Skin biopsy of petechiae

A profound alteration of posttraumatic microcirculatory flow changes follows its administration.[18] The properties of low molecular weight dextran which influence microcirculatory flow are: (1) expansion of plasma volume; (2) a change in the electric charge of the surfaces of the erythrocytes, improving or increasing erythrocyte negativity; (3) formation of a dextran-fibrinogen complex; (4) a siliconizing effect upon the injured blood vessel wall. Low molecular weight dextran has been shown to be a valuable therapeutic agent in the treatment of retarded flow within the microvasculature.[19] The mortality rate from cerebral fat embolism is less after the use of low molecular weight dextran in a dosage of 500 ml intravenously every 12 hours. Contraindications for the use of low molecular weight dextran are the presence of localized sepsis, renal failure, pulmonary edema, congestive heart failure, severe dehydration, hypofibrinogenemia, and thrombocytopenia.

Summary

Fat embolism produces a clinical syndrome with characteristic clinical findings and pertinent laboratory test results. The incidence and severity of the fat embolism syndrome is great enough to warrant a high index of suspicion. Treatment has become less empiric and more specific with the use of heparin, low molecular weight dextran, and corticosteroids.

Somapathy

The Illinois College of Somapathy is located at Elgin, Illinois, and its fond father is Dr. C. H. Murray. It appears that this science is devoted to the body suffering. The diagnostician feels around in the place where the nerves emerge from the spinal cord and adjusts them. Then he continues his good effects by applying ice cold, or material heated up to two hundred degrees at the place of adjustment. Here again is an offshoot of chiropractic and osteopathy, with which it is associated in another school. Dr. Murray promises his graduates $10,000 a year if they are successful.*

Curative Treatment Appreciated

I enjoy convalescence. It is the part that makes the illness worth while.—Shaw

Myocardial Revascularization* with Internal Mammary Artery Implants

DONALD B. EFFLER, M.D.†
Cleveland, Ohio

MORE THAN 1,500 internal mammary artery implant procedures have been performed at the Cleveland Clinic Hospital since April 1962. The decision to utilize Vineberg's[1] revascularization procedure was made after my colleague, Dr. F. Mason Sones, Jr., performed angiographic studies in two patients who had been operated upon five and six years earlier for ischemic heart disease. For each patient the diagnosis of coronary atherosclerosis was confirmed, and in each patient the implanted artery offered collateral support to the impaired coronary circulation. It is now apparent that of all the revascularization operations the internal mammery artery implant procedures have the broadest application to patients with ischemic heart disease.

Selection of Patients

To be considered a subject for revascularization surgery, a patient must undergo complete angiographic evaluation. Sones's[2] technic of selective coronary arteriography makes possible the precise appraisal of coronary arterial circulation with minimal risk to the patient. Ventriculography, which is a simple adjunctive study to coronary arteriography, helps the surgeon to assess the status of the left ventricular myocardium.

Demonstrable Deficit of Arterial Perfusion

The indications for internal mammary artery implant procedures have broadened with increased experience and postoperative evaluation. Stated simply, the patient who is selected for an implant procedure has a demonstrable deficit of arterial perfusion in the left ventricular myocardium. Such a deficit implies that there exists a functional demand for blood. The functional demand for blood, under stress, alters myocardial metabolism, and this results in angina pectoris, which is analogous to the mechanism that produces claudication in the

*See Test Your Word Score Page 1083.

†Department of Thoracic and Cardiovascular Surgery, The Cleveland Clinic Foundation, Cleveland, Ohio.

lower extremities. The commonest site of coronary occlusive disease is in the proximal anterior descending branch of the left coronary artery. Arteriographic demonstration of a significant proximal occlusion plus demonstrable collateral vessels offers the simplest means of localizing the area of functional demand.

Angina Pectoris

Many, perhaps the majority, of patients who have angina pectoris have good heart muscle. This can be determined by left ventriculography, which offers a kinetic evaluation of myocardial function. The normal left ventricular chamber ejects radiopaque dye in characteristic fashion. In contrast, the left ventricle damaged by major myocardial infarction or interstitial fibrosis that results from chronic ischemia, reflects its impaired function by improper contraction, dilatation of the chamber itself, and paradoxic motion. The cineangiographic evidence of impaired myocardial function is quantitative, depending entirely upon the extent and the localization of muscle damage. Frequently the changes will correlate with abnormal pressure readings obtained during catheterization of the left side of the heart. Interpretation of ventriculographic studies is dependent upon the experience and judgment of the observer.

Revascularization surgery by internal mammary artery implants is recommended for symptomatic patients who have demonstrable coronary arterial disease and salvageable myocardium.[3] That one or more infarctions have occurred is not contraindicative to surgical treatment, provided that adequate muscle function remains. Needless to say, the immediate and the long-term prognoses are influenced directly by the extent of irreversible myocardial damage.

Internal Mammary Artery Implant Procedures

Vineberg Technique

The first operations performed by the Cleveland Clinic team consisted of anterior implants according to the basic Vineberg technic.[4] The left internal mammary artery, dissected as a naked vessel from the anterior chest wall, was implanted in the anterior aspect of the left ventricle. Use of the naked artery, and a relatively short myocardial tunnel, limited the effectiveness of this procedure and restricted its use to those patients whose perfusion deficit was confined to the anterior wall of the left ventricle.

Sewell Pedicle

In early 1964, the Sewell[5] pedicle implant procedure was given clinical trial. Sewell's technic utilizes a long pedicle consisting of the internal mammary artery, its accompanying vein, interconnecting vessels, plus muscle, fat, and fibrous tissue. With increasing experience it became apparent that the naked artery of the Vineberg technic offered a lower-risk operation, but the bulky pedicle of the Sewell technic offered a more effective source for revascularization.

Vineberg-Sewell Implant

Combining the best features of the Vineberg and the Sewell approaches, the Cleveland Clinic team utilizes the Vineberg-Sewell implant, which may be applied to any region in the left ventricle where perfusion deficit exists.

A median sternotomy incision permits utilization either of the left or of the right internal mammary artery, or of both arteries. This approach has broadened the indications for implant procedures in patients who have ischemic heart disease. When an anterior perfusion deficit is demonstrable, either the right or the left internal mammary artery may be implanted. When the deficit exists on the lateral and diaphragmatic aspect of the left ventricle, the left internal mammary artery offers an available means for implantation. In so-called "triple vessel disease," where the perfusion deficit is almost universal in the left ventricle, a bilateral implant procedure is performed with a single operation: the right internal mammary artery is placed in an anterior tunnel, the left in a lateral and posterior tunnel.

On occasion, an implant operation is performed as a complementary surgical procedure. Patients who undergo resection of a ventricular aneurysm may benefit by a laterally placed implant. Direct attack upon a segmental obstruction of a dominant right coronary artery may also be augmented by an implant on the anterior wall of the left ventricle.

It is now apparent that the potential for internal mammary artery implant procedures and the variety of operations that utilize this basic approach are greater than originally anticipated. Either internal mammary artery can be utilized for implantation procedure, and any area of left ventricular myocardium is accessible for implantation.

Postoperative Evaluation

The outcome of a revascularization procedure for ischemic heart disease is not determined just from survival and subjective relief. Those who recall an earlier and discredited era of coronary artery surgery know that objective evaluation of the postsurgical patient is essential. Modern coronary artery surgery begins and ends with arteriography. This invaluable procedure offers precise evaluation of the potential patient who may undergo revascularization surgery, and is the only means of establishing proof that the result is a success or a failure.

Evaluation of an internal mammary artery implant procedure is best undertaken one year or longer postoperatively. Arteriography (of internal mammary artery implants) prematurely obtained provides inconclusive data. After one year the psychologic factors are less likely to influence subjective appraisal. Objective analysis by direct opacification of the implanted vessel is feasible, as maximum collateral growth will have occurred.

Results

Critics of revascularization surgery state that available reported series of surgically treated patients are not controlled and that surgical benefit in relation to the natural history of disease is not apparent. Experience at the Cleveland Clinic, less than six years since its beginning, constitutes a developmental period in revascularization surgery in which new diagnostic procedures and relatively new surgical procedures have been combined. An initially timid attitude has gradually given way to one of increased confidence and aggressiveness. The diagnostic and the surgical technics remain in a state of evolution, as members of the medical-surgical team strive for improvement and refinement. Evaluation of surgical results must take into account the preoperative status of the individual, then the success or failure of the implant procedure itself. In addition, the stability or the progress of the patient's basic, underlying coronary arterial disease must be considered. It is unlikely that any revascularization procedure, even eminently successful, will halt the atherosclerotic process itself.

Evaluation of an implant procedure requires direct opacification of the involved internal mammary artery. Complete surgical failure demonstrated by total occlusion of the implanted vessel has occurred in approximately 8 percent of those patients who underwent evaluation studies. In 92 percent of those patients who have undergone postoperative arteriography, the implanted artery is patent. In reporting the results obtained by coronary artery surgery it is difficult to avoid oversimplification. The presence of a patent internal mammary artery within the myocardial tunnel does not in itself imply successful revascularization. At the present time, results based upon internal mammary arteriography are roughly classified as patent or closed. The latter classification is obvious and needs no clarification. The patent implant is listed in one of two categories: Type A—the implant with demonstrable collateral branches to identifiable segments of the coronary circulation, and Type B—the implant without demonstrable side branches.

Demonstrable Collateral Branches

Type A: The ideal implant as determined by arteriographic study shows communication to the proximally obstructed coronary artery. The best results indicate that collateral communications are an extension of the side branches arising from the implanted vessel. Contrary to earlier beliefs, new vessels do not seem to be formed from the implant, although the possibility that they could so form is recognized.

Retrospective evaluation of the preoperative arteriograms suggests that the best implant results are those in which the affected major coronary artery was obstructed more than 90 percent of the luminal caliber and was supported by demonstrable collaterals from adjacent major vessels. Arteriographic demonstration of a direct communication between a

patent implant and an identifiable coronary artery is accepted as proof that revascularization has been accomplished in this particular area of myocardium.

No Demonstrable Collateral Vessels

Type B: Thirty-five percent of patent implants show no demonstrable side branch collateral vessels. In some implants the contrast medium is temporarily suspended within the implant and remains so for several successive heartbeats. In other implants the contrast medium runs off quickly and creates a myocardial blush and opacification of the great coronary vein. Arteriographically, Type B is a much less attractive implant than the one with demonstrable side branch communications. There appears to be some clinical correlation in regard to those patients who demonstrate the Type B patent implant; little benefit is correlated with slow arteriographic runoff, whereas appreciable improvement in symptoms is correlated with a definite myocardial blush. Retrospective analysis suggests that the Type B implant is more likely to result when the involved coronary artery was less than 90 percent obstructed and when collateral support from adjacent coronary vessels was not apparent.

As the volume of postoperative studies among the surviving patients increases, individual observations are made that enhance our understanding of the concept of the internal mammary artery implant and its clinical potential. Not infrequently, a progress study will prove that a major coronary artery has become totally occluded. Often a late progress study will demonstrate that total occlusion has occurred in a region where major infarction would logically follow—under which circumstances the presence of a functioning implant would suggest that the patient has received the desired protection that true revascularization should provide. It is also apparent by comparison of the preoperative and postoperative coronary arteriograms that the best implants result when functional demand is greatest and the involved myocardium is salvageable. This observation has prompted us to accept, for surgical treatment, patients with much more extensive disease than we would have considered four or five years ago. The change of attitude is based upon the observation that the greater the functional demand, the more likely a desirable implant will result; this extension of operative indications is accompanied by the inescapable fact that the initial surgical risk will be increased.

Summary and Conclusion

There is little doubt that Vineberg's hypothesis has been substantiated by the clinical experience of the Cleveland Clinic surgical team. True revascularization of ischemic myocardium can be provided by a properly executed internal mammary artery implant procedure. Proof of this has been established repeatedly by postoperative internal mammary arteriography.

Selection of the patient who should undergo an internal mammary artery implant procedure requires precise evidence that a perfusion deficit exists in the left ventricular myocardium and that the involved muscle is salvageable. The best results are obtained in those patients who have increasing angina pectoris and whose coronary arteriograms demonstrate nearly total or complete obstruction of a major coronary artery, with demonstrable collateral support from adjacent vessels.

Clinical Emergencies Due to Bacterial Infection

MARTIN C. McHENRY, M.D.*
RAY A. VanOMMEN, M.D.*
Cleveland, Ohio

SOME BACTERIAL infections produce clinical emergencies. The situation is acute; the period of potential reversibility is short; and the prognosis is guarded. Prompt recognition and institution of treatment, close observation, and intensive care may be required to prevent death or serious permanent disability. Often it is necessary to initiate antibacterial therapy on the basis of a presumptive etiologic diagnosis after suitable bacteriologic smears have been obtained and cultures have been started, but before the responsible organism is definitively identified. Use of potentially toxic antimicrobial drugs may be warranted when they are known to be significantly more effective than alternative ones against the suspected pathogens. We have limited this discussion to selected bacterial infections that may produce life-threatening emergencies. These include bacteremic shock caused by gram-negative bacilli, acute bacterial meningitis, fulminating meningococcemia, acute bacterial endocarditis, and staphylococcal enterocolitis.

Shock Associated With Bacteremia Due to Gram-Negative Bacilli

Bacteremia due to gram-negative bacilli now appears to be second only to hemorrhage and myocardial infarction as a cause of shock in hospitalized patients.[1] The mortality rate of this type of bacteremic shock ranges from about 40 to 90 percent. Early in this complication, patients may have fever, warm skin, rapid bounding pulse, and hypotension; later more overt signs of shock with generalized vasoconstriction may develop.[2] Pathogens most frequently isolated include *Escherichia coli, Klebsiella-Enterobacter, Pseudomonas, Proteus,* and *Bacteroides.* Polymicrobic infection is not rare. The usual sources of bacteremia are infections of the genitourinary tract, peritoneal cavity, biliary passages, gastrointestinal tract, respiratory tract, and skin.

*Department of Internal Medicine, Section of Infectious Diseases, The Cleveland Clinic Foundation, Cleveland, Ohio.

Pathogenesis

Bacteremic shock due to gram-negative bacilli often develops in patients receiving intensive medical or surgical therapy for other serious or life-threatening diseases. These diseases and therapies may be of paramount importance in the pathogenesis and eventual outcome of bacteremia due to endotoxin-producing gram-negative bacilli.[1] Among the major underlying conditions are obstruction of the urinary or biliary passages, malignant neoplasms, hematologic disorders, diabetes mellitus, hepatic cirrhosis, third-degree burns, and complications of pregnancy. In about one half of these patients, bacteremia develops after a surgical or instrumental procedure on the genitourinary, gastrointestinal, or biliary tract. Occasionally bacteremia due to gram-negative bacilli has resulted from infection at cutdown sites or from transfusions with contaminated blood.

Management

Successful management of bacteremic shock depends upon early eradication of infection and restoration of adequate tissue perfusion. This is a typical example of a clinical situation wherein it is necessary to initiate antimicrobial therapy without delay after suitable specimens of blood, body fluids, and exudates have been obtained for bacteriologic studies. Results of cultures of extravascular sites of infection (e.g., urine, operative sites), obtained during the period of observation before the onset of bacteremia, may provide a clue to the identity of the causal organisms. Certain clinical features may also suggest a causative organism. For example, *Pseudomonas* may be suspected in patients with ecthyma gangrenosum,[2] third-degree burns, or serious hematologic diseases, particularly if there is agranulocytosis; this suspicion is heightened when the patient has had predisposing antibiotics, adrenal glucocorticoids, and cytotoxic chemotherapeutic agents.[3] When there is no such clue to the identity of the organism, but bacteremic shock due to some type of gram-negative bacillus is suspected, some physicians prefer to administer combined therapy with kanamycin and chloramphenicol until the results of cultures are available. If the response to therapy in from 12 to 24 hours appears inadequate, the regimen may be altered to include polymyxin B or colistin. When the clinical picture suggests *Pseudomonas* infection, some clinicians prefer to administer polymyxin B or colistin conjointly with kanamycin until the results of bacteriologic cultures are known. However, one should be aware of the toxic effects shared by the polymyxin preparations and kanamycin, such as nephrotoxicity and a curariform reaction, and possible enhancement of their occurrence on their conjoint usage. In patients with renal insufficiency, kanamycin, colistin, and polymyxin B must be given in reduced dosage. In addition to antimicrobial therapy, surgical drainage of abscesses, or relief of obstruction of viscera may be required for control of infection in some patients.

Hemodynamic Derangements

Recent studies[4-6] have disclosed wide variations in hemodynamic derangements in patients whose disorders are diagnosed as bacteremic shock. Some patients have had evidence of a disturbance in peripheral vascular regulation, others hypovolemia, and still others cardiac defects. Accordingly, restoration of adequate tissue perfusion depends upon precise identification of the sequential hemodynamic abnormalities in individual patients with shock. When hypovolemia is a contributing factor (e.g., postoperative fluid losses, peritonitis, third-degree burn), expansion of blood volume may restore cardiac output and adequate tissue perfusion. The central venous pressure may be used as a guide to therapy. Sequential determinations of the blood volume may also be desirable. Volume expansion may be continued as long as the central venous pressure does not rise appreciably above 10 cm. of water and physical signs of heart failure do not develop. In patients with normal or low central venous pressure and shock that is not precipitated by obvious volume depletion, expansion of the blood volume with a rapid infusion of dextran may augment cardiac output and improve the circulatory status.[7] When the central venous pressure is elevated or rapidly rises to abnormal levels after infusion, fluid intake should be restricted and cardiac inotropic agents may be indicated. Vasopressor agents,

such as metaraminol and levarterenol, are now being administered less frequently to patients with bacteremic shock. These agents may be beneficial in some patients with shock who do not have hypovolemia, especially if there is little evidence of reflex vasoconstriction. Isoproterenol has been efficacious in some patients with bacteremic shock who do not respond to blood volume expansion and administration of vasopressors.[8] The value of adrenal glucocorticoids and alpha-adrenergic blocking agents in the treatment of bacteremic shock remains controversial.

Acute Bacterial Meningitis

Meningitis should be considered in patients with a history of infection of the upper respiratory tract, followed by vomiting, headache, lethargy, mental confusion, or stiff neck.[9] Diagnostic lumbar puncture should not be delayed in febrile patients who are confused or comatose. It is important to recall that newborn infants with purulent meningitis frequently exhibit a nonspecific illness without fever or nuchal* rigidity.[10]

Purulent meningitis can be caused by any one of a wide variety of bacteria. Accordingly, microscopic examination of the stained spinal fluid sediment should be performed before selection of initial therapy. Furthermore, certain clinical data also provide important clues to the most likely pathogens. If no organisms are detected on the initial spinal fluid smear, these data serve as the sole basis for selection of antibacterial therapy while awaiting the report of bacteriologic cultures.

Neonatal Meningitis.

In infants less than two months of age, enteric gram-negative bacilli, *Streptococci* and *Staphylococci* are the bacteria most commonly responsible for purulent meningitis.[10] If no organisms are observed on the initial smear of spinal fluid of an infant with purulent meningitis, kanamycin and ampicillin may be administered until the identity of the organism is known. If there is clinical evidence suggestive of a possible staphylococcal infection (e.g., furunculosis), methicillin may be administered conjointly with kanamycin until bacteriologic data are reported.

*See Test Your Word Score Page 1083.

"Nonhospital"-Acquired Meningitis in Children and Adults

In patients more than two months of age, *Hemophilus influenzae, Pneumococci* and *Meningococci* account for the majority of cases of bacterial meningitis acquired outside the hospital.[10] In children between two months and six years of age, *Hemophilus influenzae* is the most common pathogen. In children older than six years of age and adults, *Meningococci* and *Pneumococci* are the usual causal agents. *Pneumococci* are most commonly responsible for nonepidemic bacterial meningitis in patients more than 50 years of age. Meningococcal meningitis is the only type that occurs in epidemics. Petechial or purpuric skin lesions frequently develop in patients with meningococcal meningitis, but rarely with meningitis due to other bacteria[9] or to viruses.[10] Recurrent episodes of bacterial meningitis most frequently are due to *Pneumococci* or *Hemophilus influenzae,* but other organisms may be involved. Recurrent episodes of bacterial meningitis are often associated with congenital or acquired communications between the central nervous system and the external environment, persistent parameningeal foci of infection, or defective immunologic mechanisms of the patient.

Ampicillin has been described[11] as being as effective as penicillin G in the treatment of pneumococcal and meningococcal meningitis, and as effective as chloramphenicol in meningitis due to *H. influenzae.* Consequently, in patients more than two months of age, ampicillin now appears to be the drug of first choice for the initial therapy of purulent meningitis not acquired in the hospital. However, ampicillin should not be given to patients who are known to have hypersensitivity to one of the penicillins. In patients with known hypersensitivity to the penicillins, chloramphenicol might be administered as an initial agent when no organisms are detected on the pretreatment smear of the spinal fluid. Some of the possible alternative antibiotics in regard to meningococcal meningitis include erythromycin, tetracycline, or chloramphenicol; in regard to *Hemophilus influenzae* meningitis, or pneumococcal meningitis, chloramphenicol. The usefulness of the sulfonamides in initial therapy of purulent meningitis is limited by the fact that some

strains of *Meningococci* are now resistant to these agents.

Hospital-Acquired Meningitis.

Purulent meningitis acquired in the hospital is frequently due to *Staphylococci* or enteric gram-negative bacilli.[10,12] Meningitis occurring after lumbar puncture often is due to *Pseudomonas.*[13] In patients with *Pseudomonas* meningitis, the spinal fluid may exhibit a greenish fluorescence under ultraviolet light, and this finding may permit anticipation of the subsequent bacteriologic diagnosis.[13]

When no organisms are observed on the initial smear of the spinal fluid of patients with hospital-acquired purulent meningitis, we prefer to initiate therapy with methicillin and kanamycin until the results of cultures are available. In patients with meningitis due to *Pseudomonas,* it may be necessary to administer intrathecal therapy with polymyxin B.

Fulminating Meningococcemia

The presenting manifestations of fulminating meningococcemia may be fever, purpura, delirium or coma, and hypotension. Evidence of meningitis may or may not be present, and death may occur in a matter of hours. Recommended antibacterial therapy is identical to that described for meningococcal meningitis. It is now known that in the shock syndrome associated with meningococcemia (Waterhouse-Friderichsen syndrome) administration of adrenal glucocorticoids and vasopressors has not improved survival rate.[14] Recent evidence indicates that cardiac failure secondary to myocarditis is an important factor in the pathogenesis of meningococcal shock.[15] Therapy with rapid-acting cardiac glycosides and isoproterenol appears to be beneficial.

Acute Bacterial Endocarditis

Some patients with acute bacterial endocarditis may exhibit a fulminating illness with hectic fever, chills, multiple septic emboli, the appearance of new or changing heart murmurs, and congestive heart failure. Death or irreversible cardiac damage may develop rapidly when this condition is not recognized and treated promptly.[16] In patients suspected of having acute bacterial endocarditis, two or three pretreatment blood cultures should be obtained at hourly intervals, and then therapy should be initiated without delay.[17] Since more than 80 percent of cases of acute bacterial endocarditis are now caused by *Staphylococci,*[18] antistaphylococcal therapy should be administered unless some clinical clue strongly suggests the *Pneumococcus, Enterococcus* or some other species.[17] Maximal doses of a penicillinase-resistant penicillin should be given. Cephalothin or vancomycin may be administered to patients with known hypersensitivity to the penicillins. Cephalothin has been well tolerated by a majority of patients with known hypersensitivity to the penicillins; however, it should be given cautiously to those patients because allergic reactions have occurred. Vancomycin may be the preferred agent for treatment of serious infections due to occasional strains of *Staphylococci* that are not susceptible to the penicillinase-resistant penicillins or cephalothin.[19] Vancomycin must be given in reduced dosage if renal insufficiency is present.

Staphylococcal Enterocolitis

The presenting manifestations of staphylococcal enterocolitis may be a catastrophic illness with fever, abdominal distention, vomiting, profuse diarrhea, oliguria, and shock. It occurs in postoperative patients or in other persons who have been receiving broad-spectrum antimicrobial therapy. On examination of gram-stained smears, the feces or vomitus is found to be teeming with gram-positive cocci almost to the exclusion of other organisms. The mortality rate of staphylococcal enterocolitis has been high when treatment was not initiated at the time of the clinical diagnosis. Management consists of discontinuation of antibiotics the patient had been receiving, initiation of measures to restore the blood plasma volume, and administration of an antistaphylococcal antibiotic. Oral therapy with vancomycin is considered to be the preferred method of treatment for staphylococcal enterocolitis.[20,21] In fulminating cases, when oral medication cannot be retained or extraintestinal spread of the infection appears likely, parenteral therapy may be required. Under these circumstances, a penicillinase-resistant semisynthetic penicillin, cephalothin, or vancomycin should be employed.

Comment

The clinical spectrum of symptomatic bacterial infection ranges from benign, self-limited illness to rapidly lethal disease. Some factors contributing to the severity of an infection include the number and virulence of infecting organisms, the anatomic site of involvement, and the status of defense mechanisms of the host. Depending upon the etiology, the severity, and the clinical course of an infection, and upon special circumstances of the patient, the responsible physician must decide whether antimicrobial therapy should be initiated, withheld, continued, modified, changed, or discontinued. When confronted with a patient with a fulminating infection, prompt and decisive action is required to prevent death or serious permanent disability. Often it is necessary to initiate antibacterial therapy on the basis of a presumptive etiologic diagnosis *after* suitable bacteriologic smears and cultures have been obtained and before the causal agent has been definitively identified. Knowledge of the location of infection and the circumstances involved in its development will assist the physician in formulating a presumptive etiologic diagnosis. Knowledge of the antimicrobials that are likely to be effective against the suspected pathogens will provide a rational basis for selection of therapy until the results of bacteriologic cultures and in-vitro susceptibility tests are available.

Eponyms and Such

They do certainly give very strange and new-fangled names to diseases.—Plato

Novel Use for a Trombone

I was driving along in the sleigh behind Billy one moonlit, cloudless, exhilarating night. . . . The only sound was the tinkle of sleigh bells. As I approached the lonely farmhouse to which I had been summoned, I thought I heard a curious distant sound, but it was not immediately repeated. Billy and I drew up near the house, and as I climbed down from the sleigh, I heard a sudden, terrifying roar. For a second my heart stood still. It sounded to me exactly like an angry bull, and I had seen too many horrible gouges inflicted by infuriated bulls not to regard that animal with respect. I wondered if he might be loose.

I went into the farmhouse—rather fast, I should imagine—and was met by an aged, foreign-looking woman. Suddenly, another roar! To my astonishment, the blasts came from within the farmhouse walls.

"What's all the noise?" I asked.

The mother answered in broken English. "Oh, that's my daughter."

I followed the woman and the unearthly noise, to a rear room lit by an oil lamp. On the edge of the bed, which occupied most of the small chamber, sat an immense girl, about nineteen years old. . . . She held an extra large trombone to her puffed lips, and with a mighty heave she blew out a bass note resembling the roar of the angry bull I thought I had heard. She continued blasting at interals of about a minute.

Between blasts I found out what it was all about. The mother explained that it had been the custom in the family for many generations. When labor began, instead of holding her breath or crying with spasmodic pains, the expectant mother gave vent to her sufferings with a powerful gust of wind through the trombone. Not only did it relieve the agonies of muscular contractions, but also served the purpose of forcing the baby toward the outlet. I could see how it would push the diaphragm down and exert pressure on the abdominal muscles, thus promoting delivery; but I fail to see why a trombone, of all musical instruments, had to be selected.

The girl baby born that unhappy night I hope will have more compassion for her obstetrician than her mother had for me.*

*Joseph A. Jerger, M.D.: Doctor—Here's Your Hat! 1939.

Abdominal Thoracic Syndrome

Numerous upper intraabdominal conditions may cause symptoms that seem referable to the thorax, and those which appear to be abdominal in origin may arise from intrathoracic lesions, such as pneumonia, emphysema, or perforation of the lung. A subphrenic or a huge intrahepatic abscess pointing upward may cause a sequence of confusing symptoms and findings. Many symptoms of suspected gastrointestinal origin have subsequently been found to be due to coronary artery sclerosis.

Another confusing thoracoabdominal relationship is the occasional need of differentiating coronary occlusion and perforated peptic ulcer. In cardiac or other intrathoracic conditions, pain may be referred to the abdominal area due to reflex spasm of abdominal arteries or enlargement of the liver. A common example of reflex organ relationships is the action of a diseased gallbladder with cholelithiasis serving as a trigger mechanism to increase the frequency of coronary artery pain.

Transplantation of Kidneys from Cadaver Donors

Clinical Results

RALPH A. STRAFFON, M.D.*

Cleveland, Ohio

INTERMITTENT HEMODIALYSIS and renal transplantation have dramatically altered the treatment that is possible for the patient who has clinically terminal renal insufficiency. These forms of therapy, though, are not available to all patients who need them, because of an insufficient number of hemodialysis and renal transplant programs at hospitals and medical centers, a lack of adequate financial support, and a shortage of donors of kidneys.

At the Cleveland Clinic Hospital we performed our first renal transplant in January 1963, and as of October 1, 1967, 162 transplants have been performed on 139 patients. The source of kidneys in 117 renal transplants was cadaver donors. Among the advantages of using kidneys from cadaver donors is the opportunity to use both kidneys in two separate recipients, which we have done on 31 occasions to date. The one-year survival rate in this group of patients is 48 percent. It is this experience which comprises this report.

Selection and Preparation of Recipients

The selection and preparation of recipients have been discussed in a previous publication.[1] Bilateral nephrectomy was performed on nearly all the patients before transplantation. Initially, splenectomy and thymectomy were performed on randomized patients. We no longer perform thymectomy, but perform splenectomy on all prospective recipients. *The spleens obtained are used for the production of antilymphocytic globulin in horses.* After recovery from the operative procedure the patient lives near the hospital and is maintained on intermittent hemodialysis as an outpatient. The waiting period for a suitable cadaver donor is variable, but the recipient must be readily available.

Cadaver Donors

Although the results obtained in renal transplantation have been better using live donors,[2]

*Department of Urology, The Cleveland Clinic Foundation, Cleveland, Ohio.

unfortunately a suitable live donor is often not available for the patient dying of renal insufficiency. A number of recipients of various blood groups are maintained on the hemodialysis program to afford some selection of a recipient when a suitable cadaver donor becomes available.

Blood Group Compatibility

At the present time, major blood group compatibility affords the only criterion used in the selection of a suitable recipient for a cadaver donor, since time is usually too short to allow for serotyping of leukocyte antigens.[3] In a few potential cadaver donors, such as those with irreversible brain damage, there may be sufficient warning of ensuing death to obtain a blood specimen from the donor and to send it to Los Angeles for serotyping. All potential recipients waiting for cadaver donors have been previously typed, and the best recipient for the particular donor can be selected by the leukocyte serotyping technic of Terasaki.[3] Availability of serotyping services in close proximity to the transplant center, and improvements in the speed with which the serotyping can be done will make this method of selecting recipients for cadaver kidneys more practical in the future.

Securing suitable cadaver donors requires the close cooperation of all services in the hospital. When a patient is gravely ill, a member of the renal transplant team is notified, so that the suitability of the patient as a possible cadaver donor can be determined. In general, we have excluded potential donors dying from neoplasms (other than brain tumors), septicemia, and known renal diseases. When in doubt, we have adopted the policy of surgical exposure and examination of the kidneys in the operating room, after permission to use them has been obtained from the next of kin.

Malignant lesion	1
Renal artery stenosis	1
Total	86

*Both kidneys were transplanted from 31 cadaver donors; seven kidneys were obtained from hospitals other than Cleveland Clinic Hospital.

The majority of cadaver donors have had a sudden death that occurred in the operating room, the emergency room, or in the intensive care unit (Table 1). Cadaver kidneys have also been obtained from cooperating hospitals in Cleveland and in nearby communities. The technic of obtaining and preparing the cadaver kidneys for transplantation has been presented in a previous publication.[4]

Legality & Public Education

There is a great need to make more cadaver kidneys available for transplantation. Recently the Ohio Legislature enacted a bill that authorizes a living person or the survivors of a deceased person to make a gift of the body or parts thereof after death. Since the "warm" ischemia time (time from the death of the donor to the time when the kidney can be perfused and cooled to 4C) must be less than one hour, speed is essential in the salvaging of cadaver kidneys. Education of the lay public and practicing physicians in regard to the needs of and potential use of cadaver kidney transplantation is essential for continued progress in this field.

In many instances it is obvious at the time of donor nephrectomy that the kidney is nonviable or anatomically unsuitable for transplantation. Our criteria for selecting cadaver kidneys for transplantation have included: consideration of the type of death (sudden or after prolonged illness), the warm ischemia time, the gross appearance of the kidney, and the ease with which the kidney can be perfused. Histochemical technics for assessing viability are currently being studied, and the measurement of the activity of respiratory enzymes in the nephron looks most promising. The results of this determination are available within 30 to 40 minutes after death, and they appear to be a sensitive indicator of the viability of the nephron.

Transplantation

The surgical technics used in renal transplantation have been reported in detail for both living and cadaver kidneys[5] and will not be discussed in this report.

Immunosuppressive Therapy

Azathioprine* in the dosage of from 2 to 4 mg per kilogram of body weight is given immediately postoperatively to each recipient. Later this dosage is tapered to a maintenance dosage that has ranged from 25 to 250 mg per day, depending on the patient's leukocyte count and the presence or absence of manifestations of rejection of the transplanted kidney.

In addition to azathioprine, we have usually administered from 100 to 150 mg of prednisone daily, gradually tapering this dosage when rejection becomes less of a problem. Actinomycin C and local irradiation to the allograft† were utilized in some patients in whom control of rejection was a problem. Recently we have produced antilymphocytic globulin in horses, as described by Iwasaki and associates.[6] A modification of their method of separation of the globulin fraction has enabled us to obtain a much purer immunoglobulin. Since this has been available and administered, the patient has had less pain at the site of injection. No major anaphylactoid reactions have been observed in the 30 patients who received antilymphocytic globulin to date. Eighteen patients received antilymphocytic globulin late in the posttransplantation period in an effort to control a rejection episode that could not be reversed with the usual methods. Twelve patients are still alive with functioning kidneys, and one other patient is alive after nephrectomy of the rejected kidney. It appears that antilymphocytic globulin is a useful adjunct for the control of late rejection reactions.

Twelve patients were treated initially with antilymphocytic globulin as part of the immunosuppressive regimen, and although five of them subsequently died, rejection was not a problem. We have now incorporated antilymphocytic globulin, combined with azathioprine and smaller doses of prednisone, into our standard immunosuppressive program for all patients. The use of antilymphocytic globulin has allowed us to reduce the steroid dosage, and it is our hope that many of the complications due to long-term steroid therapy can be avoided.

Total	7	3	5	7	4	5	3	2

daver donors have been transplanted into 97 patients. Of these patients, 40 are alive—36 patients with functioning kidneys, and four patients who are again on the intermittent hemodialysis program awaiting a second allograft (Table 2). The length of survival and the clinical conditions of these patients are shown in Table 3. There are 26 patients alive with transplanted kidneys functioning for more than one year, and two patients have just entered their fifth year, each with a functioning renal allograft from a cadaver donor.

Complications and Postoperative Problems

The various causes of failure in our series of cadaver renal transplants are shown in Table 4.

Nonviable Kidney

Early in our series, inexperience in the selection of appropriate cadaver donors led to the transplantation of a number of kidneys already beyond salvage. Postoperative oliguria usually ensued when an allograft from a cadaver kidney was used, because of the prolonged ischemia time. Prolonged oliguria presents a problem in differential diagnosis, and may be due to acute tubular necrosis, rejection, transplantation of a nonviable kidney, ureteral obstruction, or to a problem with the vascular anastomoses. The management of prolonged postoperative oliguria has been discussed in other reports.[1,7]

Sepsis

Infection is a frequent complication that is difficult to differentiate from rejection and equally difficult to treat. It has been the direct cause of failure in three patients and has caused the death of 24. In an attempt to avoid this complication, all patients are kept in reverse isolation during the immediately postoperative period; no drains are used, and the urethral catheter is removed from the bladder in the first 24 to 48 hours unless the patient has gross hematuria that becomes a problem in management.

Urine Leakage

Leaking of urine caused failure early in four patients, and late in one patient. Leakage is an ominous complication and difficult to manage. In general there was a higher incidence of urine leakage in the kidneys from cadaver donors than in those from live donors, and in most cases it was due to rejection of the ureter. Details of the urologic complications have been discussed in another report.[8]

Hemorrhage

Hemostasis is difficult to obtain in some recipients, as the bleeding is a generalized capillary ooze. The intravenous administration of protamine sulfate during the operation, and direct transfusion from a blood donor have been helpful in controlling this type of bleeding.

Vascular Disease

Venous thrombosis occurred in two patients. In one of these the previous use of cannulas in the external iliac vein, for hemodialysis, had resulted in a thrombus, which was removed at the time of transplantation; but another thrombus formed. Massive thrombosis of both vessels, secondary to rejection, has occurred in three patients, and in each of these there was a mismatch in the ABO blood group.

TABLE 4
Causes of Failure in Renal Transplants

TABLE 5
Causes of Death after Renal Transplantation

Cause of death	Early, < 3 months	Late, > 3 months
Sepsis	13	11
Uremia	6	5
Cerebrovascular accident	4	1
Pneumonia	2	6
Gastrointestinal hemorrhage	2	0
Necrosis of bowel	1	0
Myocardial infarct	0	1
Hepatitis	0	2
Pulmonary embolus	0	1
Not known	1	0
Total	29	27

In one other patient the internal iliac artery thrombosed at the site of an endarterectomy performed to establish improved blood flow at the time of transplantation.

Rejection

Rejection reactions were a major cause of failure and accounted for the loss of nine transplanted kidneys in the first three months postoperatively, and of an additional eight homografts later in the postoperative period. Early recognition and aggressive immunosuppressive* therapy are the key to the management of rejection crises.

Agranulocytosis

Drug intoxication produced agranulocytosis in one patient and caused not only failure of the function of the transplanted kidney but the ultimate death of the patient.

Death

There have been 56 deaths among the 97 patients who received renal allografts from cadaver donors. The causes of death are listed in Table 5.

Summary and Conclusion

Between January 1, 1963, and October 1, 1967, 117 kidneys obtained from cadaver donors were transplanted in 97 patients. The one-year survival rate for these patients is 48 percent, and the overall survival rate is 38 percent.

All recipients initially were in terminal renal failure and were maintained with intermittent hemodialysis before renal transplantation. Bilateral nephrectomy was performed on all recipients, and randomized patients also underwent splenectomy and/or thymectomy. Immunosuppression was accomplished with azathioprine and prednisone, although recently, antilymphocytic globulin has been used, permitting a greatly reduced dosage of prednisone.

Numerous postoperative complications have been associated with renal transplantation, and on 45 occasions the transplanted kidney has failed. In 17 patients a second renal transplant was performed, and in one patient a third, though unsuccessful, attempt was made.

Today, renal transplantation, along with intermittent hemodialysis, must be considered as therapy for the patient with terminal renal failure. Better results in the future will depend on the development of improved tissue-typing technics, on improvement in methods of preserving and storing kidneys for transplantation, on increased availability of donors, and on continued improvement in methods of immunosuppression.

Shakespeare: Medicine

Psychological Disorders

When we meet King Lear he is already old, tired, and doubtless somewhat senile, as manifested by his petulance and rashness. Under Shakespeare's powerfully evocative pen we watch Lear's personality undergo further deterioration—to the point of mental alienation.

Shame and remorse over his own monstrous error in assessing the relative devotion of his three daughters and his subsequent inability to grasp the enormity of Fate's retribution drive him to madness.

Turned adrift by his two elder daughters Lear and his faithful fool wander a whole night on the hostile heath in a raging storm—for daylight to reveal him physically exhausted and mentally aberrant, a state wherein his youngest daughter and his doctor find him: a grotesque figure, raving and "adorned" with weeds—yet retaining shreds of that majesty that characterize him as a king.

Cordelia: Alack, 'tis he! Why, he was met even now
As mad as the vex'd sea, singing aloud,
Crown'd with rank fumiter and furrow-weeds,
With hardocks, hemlock, nettles, cuckoo-flowers,
Darnel, and all the idle weeds that grow
In our sustaining corn.
What can man's wisdom
In the restoring his bereaved sense?

Doctor: There is means, madam.
Our foster-nurse of nature is repose,
The which he lacks; that to provoke in him,
Are many simples operative, whose power
Will close the eye of anguish.

Then later:

Cordelia: How does the King?

Doctor: Madam, sleeps still.

Cordelia: Oh you kind gods,
Cure this great breach in his abus'd nature!

Doctor: So please your Majesty
That we may wake the King? He hath slept long.
Be by, good madam, when we do awake him;
I doubt not of his temperance.

Cordelia: Very well.

Doctor: Please you, draw near.—Louder the music there!

Cordelia: He wakes; speak to him.

Doctor: Madam, do you; 'tis fittest.
He's scarce awake; let him alone a while.

Lear: I am a very foolish fond old man,
Fourscore and upward, not an hour more nor less;
And, to deal plainly,
I fear I am not in my perfect mind.

Doctor: Be comforted, good madam; the great rage,
You see, is killed in him.

Note that the therapy Lear's good doctor used consisted of narcotics for sleep, stimulating music, a beloved daughter's voice, and peace.

So, Cicero Said It

While the sick man has life there is hope.—Cicero

Drug Treatment of Essential Hypertension

DONALD G. VIDT, M.D.*
RAY W. GIFFORD, Jr., M.D.*
Cleveland, Ohio

CONTROL OF HIGH BLOOD pressure with antihypertensive drugs prevents many of the complications of hypertensive vascular disease, and increases the length of survival of patients with moderate-to-severe hypertension.[1-4] Control is best achieved when blood pressure is reduced to levels as nearly normal as can be tolerated by the patient. The drug regimen must be well tolerated by the patient, because, except in unusual circumstances, it must be continued for a lifetime. Antihypertensive therapy is strictly palliative, not curative. Despite our incomplete understanding of the mechanisms of hypertension, the great advances in pharmacology of antihypertensive agents permit adequate control of blood pressure in most patients, without objectionable alterations in diet or physical activity, and with a minimum of adverse effects. This type of control requires a thorough knowledge of the drugs available, including their adverse effects and potential toxicity. This report outlines a practical approach to the drug therapy of patients with essential hypertension. The parenteral administration of antihypertensive drugs for hypertensive emergencies will not be discussed here.

Pretreatment Evaluation

Each hypertensive patient deserves a complete and thorough evaluation, preferably before therapy is initiated, unless the hypertension is so severe that delay in administering antipressor drugs would be hazardous. Adequate pretreatment evaluation is designed to answer four questions.

Does the Patient Have Sustained Diastolic Hypertension?

The term "diastolic hypertension" means persistent elevation of the diastolic blood pressure to 100 mm Hg or higher. Random determinations of blood pressure in the physician's office can be misleading. Indeed, if blood

*Department of Hypertension and Renal Disease, The Cleveland Clinic Foundation, Cleveland, Ohio.

pressure is labile, repeated determinations over an extended period may be necessary to confirm the existence of diastolic hypertension.

Is the Cause of Hypertension Remediable?

The majority of patients with hypertension suffer from primary or essential hypertension, and a family history of elevated blood pressure may provide a key to diagnosis. In a small group of patients, hypertension may be ascribed to a surgically curable problem: coarctation of the aorta, pheochromocytoma, primary aldosteronism, Cushing's syndrome, unilateral atrophic pyelonephritis or renal artery stenosis. Although less than 10 percent of all hypertensive patients have a surgically curable basis of hypertension, they should be thoroughly tested, since a cure of hypertension is preferable to lifelong medical therapy.

What Is the Patient's General Medical Condition?

The presence of an unrelated, incapacitating illness, or advanced malignant disease, may temper the physician's decision of whether to treat or not to treat the hypertension. The physician may decide against making an intensive search for a remediable lesion, or embarking upon a long, tedious, and expensive program of medical treatment if the patient has an unrelated illness that is a greater threat than hypertension is to his longevity.

How Severe Are the Associated Arteriolar Disease and Atherosclerotic Complications?

The degree of involvement of the so-called target organs—brain, heart and kidneys—is important in the selection of patients for therapy, and in the determination of the level to which blood pressure should be lowered. Atherosclerotic involvement of the target organs, along with retinal arteriolar changes, helps to formulate individual prognoses.

Choice of Drugs

Despite the array of trade names attached to various antihypertensive drugs, singly or in combination, there are only three classes of drugs that warrant discussion: oral diuretics, hydralazine*, and drugs that inhibit the sympathetic nervous system. Of the latter group of compounds, only guanethidine and methyldopa are used extensively in our practice.

Oral Diuretics (Table I)

Chlorothiazide and its many benzothiadiazine derivatives, along with chlorthalidone and quinethazone, have largely replaced Rauwolfia as the 'cornerstone' of antihypertensive therapy. The benzothiadiazine derivatives produce a transient diuresis and negative sodium balance, with a resultant reduction in plasma volume and cardiac output.[5,6] Although decrease in plasma volume may initially reduce the blood pressure, continued administration of these compounds is associated with restoration of the sodium balance, plasma volume, and cardiac output, but not the high blood pressure. The mechanism of chronic maintained antipressor effect remains unclear, although a direct effect upon peripheral arteriolar resistance has been postulated.[7] When orally administered in the suggested doses, all the oral diuretics are comparable in their antihypertensive properties and potential toxicity. In the treatment of severe or malignant hypertension, they provide valuable adjuncts to therapy, as they augment the antipressor effects of ganglion-blocking or sympatholytic* drugs. This permits better control of hypertension with smaller doses of the more potent agents. To a lesser degree they also augment the antipressor response to Rauwolfia compounds and to hydralazine. Oral diuretics should be prescribed with caution for patients with impaired renal function or with gout, since they tend to increase the blood concentrations of urea and uric acid in susceptible patients. Simultaneous administration of probenacid (Benemid) or allopurinol (Zyloprim) will usually prevent the hyperuricemia induced by administration of these drugs, and will make it possible to employ those agents in patients who have gout. Other adverse effects of chlorthalidone, quinethazone, and the benzothiadizine derivatives include hypokalemia, gastrointestinal irritation, weakness, dry mouth, impairment of glucose tolerance, pancreatitis, skin rash or photosensitivity, and, rarely, blood dyscrasias.

Spironolactone and triamterene do not produce potassium depletion, yet they have not achieved the popularity of the kaliuretic drugs.

*See Test Your Word Score Page 1083.

Spironolactone has a modest antihypertensive effect, but it is expensive and must be administered four times daily. Triamterene is a weak diuretic and has little, if any, antipressor action. Either spironalactone or triamterene will minimize or eliminate the hypokalemia induced by therapy with the benzothiadiazine derivatives, chlorthalidone, or quinethazone.

Usually, the hypokalemia induced by these agents is not serious enough to require potassium supplementation or adjuvant therapy with spironolactone or triamterene unless the patient is also receiving digitalis. When potassium supplementation becomes necessary, we prefer to administer it separately in liquid or effervescent-tablet form. Although many of the oral diuretics are available in a combination form containing supplemental potassium, the available potassium rarely is adequate for repletion, and the enteric-coated tablets of this type have been associated with ulcerations of the small intestine.[8]

Ethacrynic acid (Edecrin), a compound chemically unrelated to other oral diuretics, has an antipressor effect comparable to the benzothiadiazine derivatives. A new compound, Furosemide (Lasix), will require more study to prove its efficacy as an antihypertensive drug. Both of these last-mentioned agents are potent diuretics.

Hydralazine (Apresoline)

Hydralazine decreases total peripheral resistance and increases the cardiac stroke volume and heart rate. The resultant reduction in diastolic blood pressure may be greater than the reduction in systolic pressure, and the redistribution of blood flow favors the splanchnic and renal circulations.[9,10] Hydralazine when properly used is a safe and effective antipressor agent. Because of the high incidence of adverse effects associated with its administration, it should not be used as the sole antipressor agent. The adverse effects include headache, palpitations, tachycardia, flushing, and occasionally nausea and vomiting. More serious complications include exacerbation of coronary insufficiency, fluid retention, fever or toxic psychosis. These adverse effects can be largely avoided if the patient is pretreated for several days or weeks with another antipressor agent. A late toxic reaction characterized by a 'collagen-like' syndrome resembling lupus erythematosus rarely occurs if the total dosage of hydralazine does not exceed 300 mg per day.

TABLE 1

Oral Diuretic Agents Used in the Management of Essential Hypertension

Drugs	Trade name	Size of tablet, mg*	Usual daily dose, mg*
Benzothiadiazine derivates			
Chlorothiazide	Diuril	250 or 500	1000-1500**
Hydrochlorothiazide	Hydrodiuril	25 or 50	100-150**
	Esidrix Oretic	25 or 50	
Hydroflumethiazide	Saluron	50	100-150**
Bendroflumethiazide	Naturetin	2.5 or 5	10-15
Trichlormethiazide	Naqua	2 or 4	8-16
	Methahydrin	2 or 4

Benzthiazide	Exna	50	100-150**
Polythiazide	Renese	2 or 4	4-12
Cyclothiazide	Anhydron	2.0	2-4
Phthalimidine derivative			
Chlorthalidone	Hygroton	50 or 100	50-100
Quinazoline derivative			
Quinethazone	Hydromox	50	100-150**
Aldosterone antagonist			
Spironolactone	Aldactone-A	25	100-400†

*Given once daily unless otherwise indicated.

**Usually divided and given twice daily.

†Usually divided and given four times daily.

Sympathetic Nervous System Inhibiting Drugs (Table 2)

The compounds that block the sympathetic nervous system act by preventing release, by competitive inhibition, by acting as "false transmitters" or by depleting body stores of catecholamines. Of this group of agents, only Rauwolfia derivatives, guanethidine, and methyldopa are extensively used today.

Rauwolfia alkaloids presumably act by depleting tissues of their catecholamine content, yet do not produce clinical orthostatic hypotension from the doses used. The alkaloids of Rauwolfia are not potent antipressor agents and frequently produce symptomatic adverse effects. Rauwolfia, to be used orally, has been largely replaced by diuretic compounds, since they produce fewer adverse effects and have proved more potent than Rauwolfia in enhancing the responses to other antipressor agents. Objectionable effects include nasal congestion, myalgias, edema, laxation, and gastric hyperacidity. Psychic effects may occur, such as lassitude or disturbing nightmares. A serious psychic reaction is the development of a true depression that may be so severe as to require a psychiatrist's care, but so occult as to escape detection. Depression does not usually occur if the dosage of various Rauwolfia preparations does not exceed the equivalent of 0.25 mg of reserpine daily.

Ganglion-blocking drugs competitively inhibit the action of acetylcholine, the chemical mediator of transmission of nerve impulses at all autonomic ganglions—parasympathetic and sympathetic. Sympathetic inhibition results in reduced arteriolar vasoconstriction, decreased venomotor tone, and increased venous pooling of blood in peripheral vascular beds. Venous return is impaired in the upright position, cardiac output decreases, and orthostatic hypotension, weakness, and syncope occur. The ganglion-blocking agents in common use today are pentolinium and mecamylamine, and doses of either agent are divided and given four times daily. Their greatest disadvantage is the inhibition of the parasympathetic nervous system, resulting in unpleasant or intolerable

TABLE 2

Antihypertensive Drugs That Depress the Sympathetic Nervous System

Drugs	Trade name	Size of tablet, mg	Usual daily dose, mg*

*Given once daily unless otherwise indicated.
**Usually divided and given 3 or 4 times daily.

effects that include blurred vision, dry mouth, constipation, urinary retention, and impotence. The oral diuretics potentiate the effects of ganglion-blocking drugs and may allow blood pressure control with smaller doses. Nevertheless, these agents have all but disappeared from clinical practice since the development of drugs that selectively inhibit the sympathetic nervous system, thus avoiding the effects of parasympathetic blockade.

Guanethidine sulfate (Ismelin) specifically blocks the sympathetic nervous system by inhibiting release of norepinephrine from postganglionic nerve endings.[11] It also depletes tissue stores of catecholamines. In contrast to ganglion-blocking drugs, guanethidine is long-acting, its effect lasting from five to seven days, and tolerance to it does not occur. Like ganglion-blocking agents, it reduces blood pressure more in the vertical than in the horizontal position. Guanethidine has almost eliminated the need for ganglion-blocking drugs, as its antipressor effect is as potent; yet it does not induce the troublesome parasympathetic effects. Because of its long duration of action, guanethidine can be administered as a single daily dose, preferably at the same time each day. The principal adverse effects are orthostatic hypotension, exertional weakness, bradycardia, diarrhea, and impotence or failure of ejaculation. Anticholinergic* drugs will help to control troublesome diarrhea. Potentiation of the antipressor effect of guanethidine by simultaneous administration of oral diuretics will usually permit significant reduction in the dosage requirements for guanethidine.

Methyldopa (Aldomet) inhibits decarboxylase, depletes tissue stores of norepinephrine, and acts as a 'false transmitter' at the sympathetic neuroeffector junction.[12] Alpha-methyl norepinephrine, a metabolite of methyldopa, displaces norepinephrine at the storage sites, and produces a weak pressor response when released by sympathetic stimulation. The antipressor potency of methyldopa is similar in magnitude to Rauwolfia compounds or to oral diuretics. When administered in combination with a diuretic, the antipressor effect exceeds that of combination therapy with a diuretic and either Rauwolfia or hydralazine, and the effect approaches that of guanethidine. Treatment with methyldopa alone or in combination with a diuretic is less likely to result in orthostatic hypotension than is treatment with a ganglion-blocking drug, guanethidine, or pargyline. For this reason, methyldopa is safer than these other drugs in the management of hypertension associated with cerebrovascular or coronary insufficiency. Patients with renal failure demonstrate unusual sensitivity to the antipressor effect of methyldopa, and in these patients it should be used without a diuretic, since renal failure is a contraindication to chronic therapy with diuretics. Adverse effects include mild drowsiness, dry mouth, fever, nasal congestion, depression, abnormal liver-function tests (with or without jaundice), impotence, or fluid retention. Approximately 15 percent of patients receiving methyldopa demonstrate a positive Coombs' test which rarely is associated with hemolytic anemia.

Pargyline hydrochloride (Eutonyl) is a nonhydrazine monamine oxidase inhibitor whose antipressor potency approximates that of guanethidine.[13,14] Its effect is prolonged and cumulative; it is prone to produce orthostatic hypotension, and adjustments in dosage must be undertaken with extreme care. The response to pargyline is enhanced by concomitant treatment with an oral diuretic. Ingestion of foods and beverages containing large amounts of tyramine (certain types of cheese, and beer and wine) may precipitate a dangerous hypertensive crisis in patients taking pargyline. Methyldopa, guanethidine, antihistaminics, sympathomimetic* drugs and other monamine oxidase inhibitors should not be given to patients receiving pargyline. Other troublesome effects include nausea, vomiting, diarrhea, insomnia, impotence or failure of ejaculation, or both. Because of the many drug and food incompatibilities, and because the antipressor effect is not superior to that of guanethidine, pargyline is seldom used.

Therapeutic Regimen in Uncomplicated Hypertension

The key to successful management of hypertension rests with individualization of the therapeutic regimen. The selection of drugs must be influenced by the presence or absence of cardiac, cerebral, or renal complications, by the pretreatment level of the diastolic blood pressure, and by the patient's acceptance of

*See Test Your Word Score page 1083.

the recommended medication. *We do not usually recommend antipressor drugs for patients with labile hypertension in whom the diastolic pressure is not persistently elevated.* Although sustained diastolic hypertension may eventually develop in many of these patients, there is no good evidence that medical treatment will alter this natural course of events. Patients with systolic hypertension (blood pressure higher than 220 mm Hg) may benefit from an oral diuretic. So long as the diastolic blood pressure does not exceed 100 mm Hg and the systolic pressure does not exceed 220 mm Hg, treatment is probably not necessary unless heart failure is present.

Mild-to-Moderate Uncomplicated

Mild-to-moderate uncomplicated hypertension exists when the diastolic blood pressure ranges from 100 to 120 mm Hg in the absence of cardiovascular, renal, or central nervous system dysfunction. Treatment should be deliberate, preferably with the administration of one drug at a time, allowing time for the effect of each agent to be evaluated before administration of another drug is initiated (Table 3). We prefer to initiate treatment with an oral diuretic, which will control the diastolic blood pressure in 40 percent of patients in this category. Methyldopa can be added after from three to six weeks, with gradual increases in dosage to as much as 0.5 g four times daily, if necessary to keep diastolic blood pressure below 100 mm Hg. If step C (Table 3) becomes necessary, administration of guanethidine may be started in a dose of from 10 to 12.5 mg once daily. The dosage may be increased by this amount every two or three weeks, until adequate control of blood pressure is achieved or until adverse effects become intolerable. Hydralazine may be used as an adjuvant agent. It may be worthwhile to add hydralazine in increasing doses to as much as 75 mg four times daily. If no appreciable lowering effect on the blood pressure has been obtained, or if intolerable side effects occur, treatment with hydralazine should be discontinued before proceeding to step C (Table 3).

Severe Uncomplicated

Uncomplicated severe hypertension exists when the diastolic pressure is consistently higher than 120 mm Hg, or when retinal hemorrhage, exudate, or papilledema has occurred. It is now imperative to bring the blood pressure under control quickly, even though cardiovascular or renal complications have not yet developed. The treatment timetable should be expanded with increments in dosage and addition of new drugs being made at more frequent intervals than recommended for the mildly or moderately hypertensive patients. Therapy is initiated with an oral diuretic in optimal dosage, and guanethidine from 10 to 25 mg once daily (Table 3). The dosage of guanethidine should be increased by 10 or 25 mg every three or four days until hypertension is controlled or intolerable effects occur. Treatment is best started in the hospital, but if this is not possible it may be guided by both supine and standing blood pressures obtained two or three times daily at home. When hypertension is not controlled satisfactorily without intolerable effects, we proceed to step B (Table 3) with the addition of methyldopa in doses to as much as 0.5 g four times daily. When guanethidine is ineffective, or when it produces intolerable effects, a ganglion-blocking drug or pargyline may be substituted in combination with the oral diuretic. Methyldopa may be used in combination with a ganglion-blocking drug, but it should not be used concomitantly with pargyline.

Management of Complicated Hypertension

In managing hypertension that is complicated by impairment of cerebral, cardiac, or renal function, special precautions are indicated.

TABLE 3
Outline for Construction of Therapeutic Regimen

Steps in construction of program	Drugs	
	Preferred	Alternate
Mild-to-moderate, uncomplicated hypertension		
Step A	Oral diuretic	Rauwolfia
Step B	Methyldopa	Hydralazine
Step C	Guanethidine	
Severe, uncomplicated hypertension		
Step A	Oral diuretic plus Guanethidine	Oral diuretic plus Ganglion-blocking drug or Pargyline
Step B	Methyldopa	

Congestive Heart Failure

Left ventricular failure in the absence of coronary artery insufficiency is best managed by combination therapy with an oral diuretic and either methyldopa or guanethidine. Sometimes three drugs may be used in combination. Digitalis and dietary salt restriction are also required. Hydralazine may increase cardiac output and cardiac work and is not recommended for hypertensive patients with congestive heart failure.

Coronary and Cerebral Artery Insufficiency

Antipressor therapy should be withheld for from four to six weeks after acute myocardial or cerebral infarction unless hypertension is severe. Thereafter, treatment is instituted as outlined previously. Ismelin, ganglion-blocking drugs, and pargyline must be used with extreme caution, because of their tendency to produce orthostatic hypotension and the threat of increasing vascular insufficiency. Hydralazine should be used with extra caution for patients who have symptomatic coronary disease, because the drug sometimes aggravates coronary artery insufficiency. If hypertension cannot be controlled by an oral diuretic in combination with methyldopa, guanethidine may be added cautiously in small doses.

Renal Failure

Methyldopa and hydralazine are particularly useful in managing hypertension in the presence of renal failure, because they lessen the risk of orthostatic hypotension and consequent compromise in renal blood flow. Oral diuretics should be omitted when values for blood urea exceed 100 mg per 100 ml, unless they are used intermittently for the control of fluid retention. To control severe hypertension in azotemic patients, it may become necessary to use guanethidine in combination with methyldopa or hydralazine. Antipressor therapy should be modified or abandoned if reduction in blood pressure results in further significant elevation in the blood urea concentration. Dietary limitation of protein intake is helpful, and a liberal fluid intake should be encouraged, provided that urinary output is satisfactory.

Summary

A practical approach to the drug treatment of essential hypertension is outlined. The successful control of blood pressure depends upon the skill of the physician in devising a program that will control blood pressure with minimal adverse effects, and upon the reliability of the patient to follow the medical regimen strictly. The control of blood pressure prevents many of the cardiac, cerebral, and renal complications of hypertensive vascular disease, and drug treatment is, therefore, warranted for most patients with sustained diastolic hypertension.

Nobel Prize Winners In Medicine and Physiology

Robert Barany 1914

For his work on the physiology and pathology of the vestibular apparatus

"As a young otologist I practiced in the clinic of Privy Councillor Professor Politzer in Vienna. Among my patients there were many whose ears I had to flush out. A number of these patients complained of dizziness after the flushing procedure. It naturally occurred to me to examine their eyes, and there I observed marked nystagmus. I made note of this observation. After a while, when I had collected about twenty observations, I compared them and was surprised to find the same observations recorded every time. One of my patients whom I syringed explained to me: 'Doctor, I only get dizzy when the water is not warm enough. When I flush out my ears for myself at home and use warm enough water, I don't get dizzy.' Thereupon I called the attendant and instructed her to give me warmer water for the flushing process. She explained that the water was warm enough. I retorted that if the patient found the water too cold, we had to adjust ourselves to the patient. The next time she put very hot water in the bulb of the syringe. When I syringed the patient, he cried out: 'But Doctor, the water is much too hot; now I'm becoming dizzy again.' Hurriedly I observed the patient's eyes, and noticed that now the nystagmus was exactly opposite in direction to that seen earlier when syringing with water that was too cold. Then in a flash it became clear to me that naturally the temperature of the water was responsible for the nystagmus."

From his studies Barany concluded that the nystagmus was the result of a reflex initiated in the semicircular canals and *ergo; failure* of such syringing to produce nystagmus must indicate disease or destruction of the semicircular canals: a supposition he proceeded to verify by surgery.

Barany's irrigating test is now used extensively to diagnose vestibular disease.*

Plexiglas Hip

In 1948 Khirurgiya (Surgery), a Soviet medical journal, published an extremely interesting article by Professor Dikhno, of Khabarovsk. It describes an operation involving the use of plexiglas.

A 17-year-old youth was unable to walk because his right leg, folded up to his stomach, could not be straightened. Tuberculosis of the hip joint had made a cripple of the boy, and though the disease had subsided, it had done irremediable damage.

Professor Dikhno operated on the youth. The head of the femur, partially destroyed by the disease, had lost its normal shape.

The professor removed the bone adhesions and scars. He also extracted the affected parts of the bones. In place of the former socket the professor fashioned a new one. He then peeled off the affected coating of the head of the femur, causing it to become much thinner. That was sad, since the head was no longer solid enough to support the weight of the trunk. Moreover, it was too small for the newly-scooped socket. But Professor Dikhno enlarged it to the desired size. He put a plexiglas cap on it. The cap was an exact fit.

A month later the operated leg was back to normal. It bent and extended readily. The patient was able to walk.*

Some Important Colonic and Rectal Polyps

WILLIAM A. HAWK, M.D.*
FRANK L. WEAKLEY, M.D.†
RUPERT B. TURNBULL, Jr., M.D.†
Cleveland, Ohio

DORLAND'S MEDICAL DICTIONARY[1] defines a polyp as a "morbid excrescence, or protruding growth from the mucous membrane." In the past, the term classically applied only to a growth on the mucous membrane of the nose, but now it includes such protrusions from a mucous membrane in any part of the body.[2] The colon and, in some instances, the small intestine are hosts to a considerable variety of polyps. Although the adenomatous or papillomatous polyp is the most common, there are other types, each with its distinctive histologic pattern and characteristic biologic behavior. Table I lists a classification that is useful in considering colonic and rectal polyps, and is based upon the clinico-pathologic features of the various polypoid lesions.

In this report the less common but clinically important varieties of polyps are discussed. The common adenomatous or papillomatous polyps have been the subject of a great number of publications, so they will not be considered in detail in this report. In addition, adenomatous polyps are rarely found in childhood unless the patient has familiar polyposis.

Juvenile polyps

Symptoms

Juvenile polyps, as the term implies, occur in childhood and usually are noted as a result of rectal bleeding. Generally the bleeding is red or dark-red and without clots. Blood may be mixed with the feces. Pain is an inconstant feature and, when present, is most frequently of a crampy nature. The polyps may prolapse from the rectum. They may be single or multiple, and for an unaccountable reason boys are more often affected than girls.[2]

Pathology

Juvenile polyps grossly are pedunculated polypoid excrescences, each one comprised of a cylindric stalk attached to a smooth spheroid-

*Division of Pathology, The Cleveland Clinic Foundation, Cleveland, Ohio.

†Department of General Surgery, The Cleveland Clinic Foundation, Cleveland, Ohio.

al tissue mass (Figure 1). In our experience the largest polyp was 2.0 cm in diameter, but polyps up to 3.0 cm have been described.[3] The polyps are deeper red than the normal colonic mucosa, and the cut surface shows a large number of small cysts containing glistening mucoid material. Rarely foci of hemorrhage and ill-defined areas of increased firmness may be present. The polyps histologically are comprised of various-sized colonic glandular structures enmeshed in abundant stroma (Figure 2). Many of the glands are cystically dilated, irregular in contour, and filled with mucus. Frequently the epithelium of the dilated cystic gland is atrophic and notably flattened. An occasional gland may assume a bizarre or complex shape through partial obstruction of a gland orifice. The stroma is distinctive and abundant; it is highly cellular and resembles granulation tissue, being formed of fibroblasts, reticulum fibers, and numerous widespread fine capillaries. In many foci there is an infiltration by lymphocytes and plasma cells, and occasionally there is lymph follicle formation. Histiocytes, neutrophils, and occasionally eosinophils may also be noted in patchy areas. The density of this chronic inflammatory infiltrate is variable and influenced by the ulceration of the surface epithelium that characteristically encompasses the polyps.

The stalks of the juvenile polyps are formed of typical colonic mucosa complete with the muscularis mucosae and a small amount of submucosa. The muscularis mucosae ends abruptly at the zone of attachment of the polyp and does not contribute to the stroma of the polyp. The enveloping single-layered mucus-secreting epithelium of the polyp joins the surface epithelium of the stalk without a transition zone. The stroma closely resembles granulation tissue, or, as Morson[4] interprets it, ". . . it simulates primitive mesenchyme." We share Morson's[4] view that these lesions represent hamartomas of the mucosal connective tissue, though Roth and Helwig[5] have suggested that the juvenile polyp represents a polypoid transformation of a local submucosal inflammatory process. Juvenile polyps do not appear to be predisposed to malignant change.

TABLE I
Classification of Polyps of the Colon and Rectum

- A. Developmental, congenital, familial polyps
  - 1. Juvenile
  - 2. Juvenile polyposis coli
  - 3. Peutz-Jeghers syndrome
  - 4. Familial polyposis
- B. Inflammatory polyps
  - 1. Pseudopolyps (chronic ulcerative colitis)
- C. Neoplastic polyps
  - A. Of colonic mucosa
    - 1. Adenomatous or papillomatous
    - 2. Carcinoid
  - B. Of tissues other than mucosa
    - 1. Lymphoid polyp (benign lymphoma)
    - 2. Lipoma
    - 3. Fibroma and neurofibroma
    - 4. Leiomyoma
    - 5. Hemangioma

Treatment

No carcinomas of the colon or of the rectum arise from such polyps. Only symptomatic ju-

B, The "fingers" of the grasping instrument are shown opened. C, After visualization of the polyp through the diagnostic proctosigmoidoscope, the clinician passes the grasping instrument into the proctosigmoidoscope. D, The polyp has been grasped. E, the proctosigmoidoscope is being withdrawn. F, The operating proctoscope is being passed around the grasping instrument. G, Traction on the grasping instrument has delivered the polyp into the range of the proctoscope for easy removal by snare, ligature, or forceps.

venile polyps need be excised, and then by the most conservative measures possible. Bleeding is the most common indication for removal. It should also be remembered that in many instances juvenile polyps will separate spontaneously from the wall. If completely removed they do not recur.

When there are multiple small juvenile polyps, coagulation suffices (Figure 3A, B). It is well to remove larger polyps, if possible, because of the danger of intussusception or prolapse of the polyp. If the polyp can be seen through the proctosigmoidoscope, it can be removed. If it is in the rectum—especially if on the retroperitoneal wall—it can be removed by snare or forceps without anesthesia (Figure 4 A-D). If it is in the sigmoid, it can be grasped through a diagnostic proctosigmoidoscope and then brought down to the level where it can be removed easily through an operative proctoscope. This should be done with anesthesia (Figures 5 A-G). Occasionally excision must be performed at laparotomy and colotomy (Figures 6 A-J). Asymptomatic colonic polyps, once the diagnosis has been established, need not be removed.

Juvenile Polyposis Coli

Veale and his colleagues[3] have reported a series of 11 cases of multiple juvenile polyps, giving the histopathologic and clinical features, and the family histories. There were eight girls and three boys in the series, a reverse of sex incidence of that noted for isolated juvenile polyps. Polyps were found throughout the colon in seven of the patients, but in four were limited to the rectosigmoid. Of interest is that the ileum was affected in two patients. Subsequent cases have been reported by others.[6]

The histology of the lesions of juvenile polyposis coli was identical to that of juvenile polyps. In some of the cases there was a family history of juvenile polyposis or of cancer or of both types of lesions of the large bowel. Veale and associates[3] postulate that the disease is brought about by the modification of the action of the gene for adenomatous polyposis coli by an allele* received from a normal parent. Isolated cases of the disorder are considered to arise from fresh mutations.

*See Test Your Word Score page 1083.

According to present knowledge and to our own clinical experience, treatment should be conservative, since, as yet, cancers have not been found in this group of patients. Occasionally resection may be required in cases of troublesome bleeding, intussusception or protein loss.

Peutz-Jeghers Syndrome

Mucocutaneous pigmentation and intestinal polyposis together comprise Peutz-Jeghers syndrome.[7,8] The polyps develop both in the large and in the small intestine, and occasionally in the stomach. Gastrointestinal bleeding, abdominal pain, and intussusception of segments of the intestine are the most frequent symptoms. The disorder is familial and is thought to be inherited as a simple mendelian dominant trait.

The intestinal polyps grossly resemble the common colonic papillomatous or adenomatous polyps. They are finely fissured, soft, pink, irregularly spheric, ranging in largest diameter from a few millimeters to approximately 2.5 cm. A slender but well-defined stalk or pedicle is always present. The basic histologic appearance of the polyp in Peutz-Jeghers syndrome is that of an arborizing fibromuscular stroma that appears to originate from a central smooth-muscle mass (Figure 7). This muscle mass appears to arise in the muscularis mucosae of the intestine and is continuous with it. The epithelial component of the syndrome closely resembles the normal mucosa of the gastrointestinal tract, in which the polyp is located, and is comprised of typical intestinal glands enmeshed in a lattice-work of fine fibrous tissue similar to that of the lamina propria of the normal gastrointestinal tract. As in the normal lamina propria, there is an interstitial infiltrate of a few polymorphonuclear leukocytes, plasma cells, and histiocytes. An important feature is the relationship of this mucosa to the supporting fibromuscular stroma; it is identical to the relationship of mucosa to muscularis mucosae. The arborizing fibromuscular stroma is formed principally of smooth muscle in the central portions of the lesion, but as one approaches the more peripheral areas of the polyp, the smooth-muscle components become discontinuous, though in most areas wisps of smooth muscle can be identified. The grandular component of these polyps is formed of typical tubular intes-

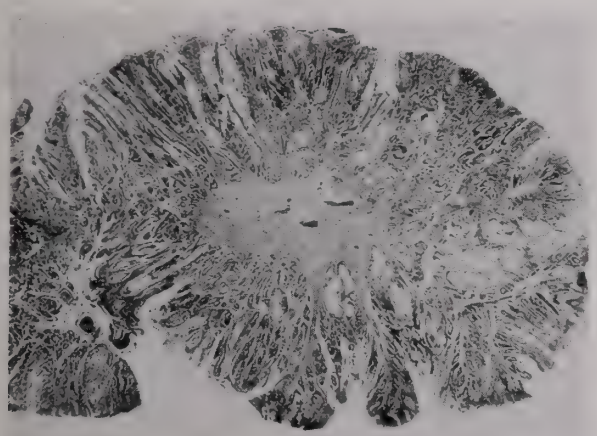

Fig. 7—Typical polyp of Peutz-Jeghers syndrome. The arborizing fibromuscular stroma is clearly apparent. H + E, methylene blue, ×7.

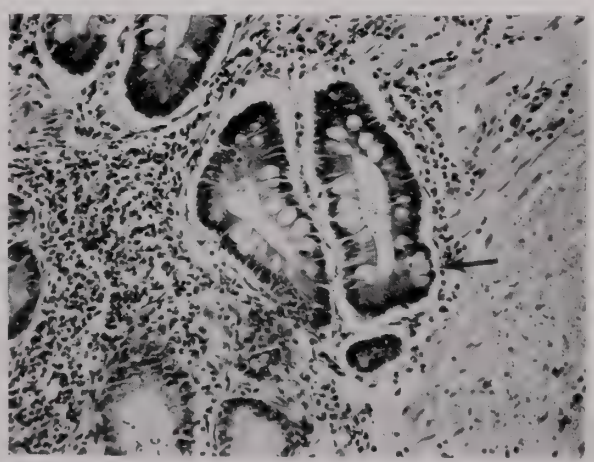

Fig. 8—Paneth's cells (arrow) are readily found in the polyps of the small intestine in Peutz-Jeghers syndrome. H + E, methylene blue, ×200.

tinal glands, some of which may become distorted or cystically dilated because of obstruction of the orifices. In the instance of small intestinal polyps of Peutz-Jeghers syndrome, formations closely resembling crypts of Lieberkühn can be identified, and in the base of these crypts one can frequently find Paneth's cells and argentaffin cells (Figure 8). In the colonic polyps, however, Paneth's cells are not usually found because they are not frequent inhabitants of the colonic mucosa.

Bartholomew and associates[9] have considered these polyps to be hamartomas. This seems a logical concept in view of the microanatomy of the polyps, which appears to be the result of a localized arborizing proliferation in the muscularis mucosae. Histologically the complex fibromuscular core is continuous with the muscularis mucosae of the intestinal tract, and the mucosal covering is essentially normal. Morson[4] suggests that the mucosa is abnormally placed. The presence of Paneth's cells and argentaffin cells would seem to confirm the normalcy of the mucosal covering.

Although Peutz[7] in his original consideration noted "malignant degeneration" of the polyps in three of seven patients, metastasis and death due to malignant disease were not established. The possibility of histologic misinterpretation of glandular structures enmeshed in the fibromuscular stroma as polypoid adenocarcinoma may explain this observation (Figure 9). A documented case of malignant degeneration and metastasis in the Peutz-Jeghers syndrome has been reported by Achord and Proctor.[10] The incidence of such a catastrophe, however, seems so extremely low that the recommendation for surgical treatment should be limited to the relief of obstruction and bleeding.

Comment

The polyps considered above are highly distinctive and different from the common papillomatous or adenomatous polyps in at least several respects. Grossly papillomatous polyps are pedunculated, finely fissured or even finely villous, lacking the smooth external surface of juvenile polyps that are further characterized by punctuating mucous cysts and small patches of ulceration. Polyps in the Peutz-Jeghers syndrome are less distinguishable grossly, but usually are not so finely fissured. The stroma

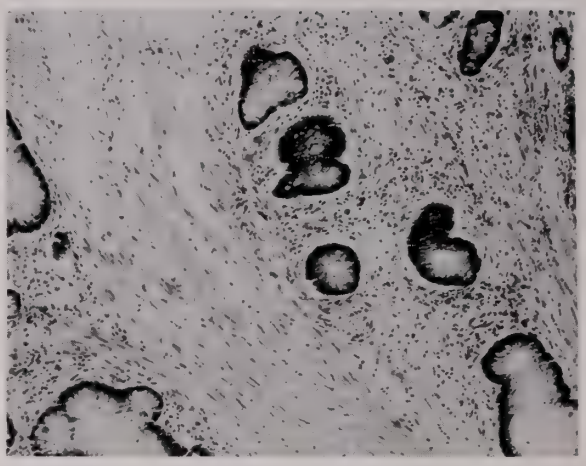

Fig. 9—Polyp of Peutz-Jeghers syndrome, showing normal colonic glands entrapped in the fibromuscular stroma, a feature that may erroneously be interpreted as stromal invasion. H + E, methylene blue, ×100.

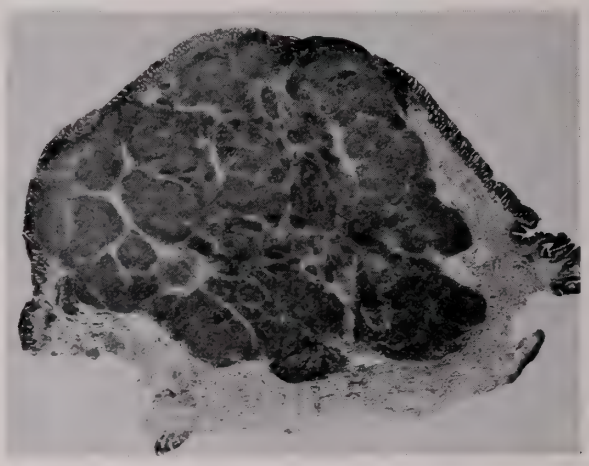

Fig. 10—Lymphoid polyp formed of the typically sharply demarcated lymph follicles. H + E, methylene blue, ×6.

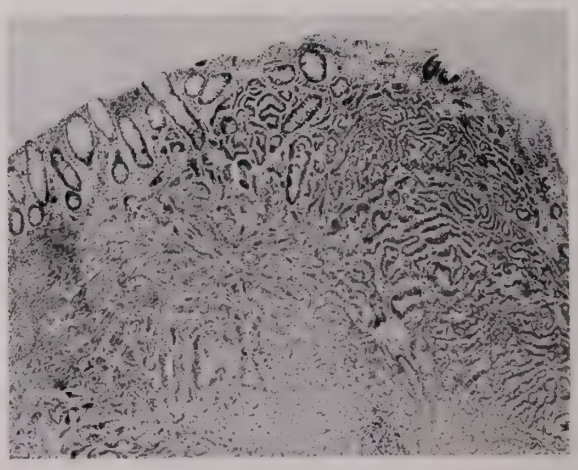

Fig. 11—A polypoid carcinoid showing the uniformity of the argentaffin cells and the invasion of submucosa and muscularis. H + E, methylene blue, ×50.

of adenomatous or papillomatous polyps is fibrous and vascular and is most abundant at the hilum or point of attachment of the polyp stalk, becoming quite inconspicuous at the periphery of the lesion. The mesenchymal appearance of the stroma of juvenile polyps and the smooth muscle component of Peutz-Jeghers polyps are certainly distinctive features. In addition, the epithelium of these polyps demonstrates its neoplastic qualities by such alterations as pseudostratification, hyperchromatism, and increased mitotic activity. In some polyps, foci of carcinoma in situ may be found. These epithelial features have not been observed as yet in juvenile polyps or polyps of Peutz-Jeghers syndrome.

The principles of treatment of patients with juvenile polyps are similar to those of the therapeutic management of patients with Peutz-Jeghers syndrome. Conservative removal of symptom-producing polyps is indicated.

Lymphoid Polyps

These rather uncommon lesions occur usually as round, mound-like polypoid masses in the rectum. They are rarely pedunculated. They are covered by a smoothed-out colonic mucosa. Ulceration, with secondary inflammatory changes, is common. A cross section of one of these lesions reveals a sharply circumscribed, rather homogenous, grayish mass of tissue in the submucosa, which elevates the mucosa. Histologically this polyp may be considered as a colonic tonsil without crypts, for it is formed of well-defined, well-differentiated lymphoid tissue, complete with typical germinal centers (Figure 10). Small numbers of mitoses may be seen within the germinal centers. The lymphocytes about these centers are mature, and miototic figures are not readily found there.

These excrescences are usually found in the rectum, principally in the lower third part. Rectal bleeding, prolapse of the polyps, and pain are the most common presenting symptoms. Cornes, Wallace, and Morson,[11] and Helwig and Major[12] have written about these lesions and have applied the brief term *benign lymphoma* to them. In their experience and in ours, none of these polyps have been associated with systemic lymphoma. However, in the series from St. Mark's Hospital, carcinoma of the rectum was associated in seven of 100 patients.[11] Therapy of these polyps has been conservative, usually limited to simple removal or electrocoagulation.

Carcinoid Tumors

The carcinoid tumor of the rectum is a gritty hard polyp. The original appears to be from the depths of the mucosa, and frequently the bulk of the tumor mass is present in the submucosa, and the lesion is entirely covered by normal colonic mucosa. The cut surface may be yellowish or grayish-white and is usually quite firm. Histologic section reveals rather distinctive uniform hyperchromatic small-to-medium-sized cells arranged in festoons or in a glandular pattern (Figure 11). Mitotic figures are extremely rare. The tumors are locally infiltrative and may invade the muscularis propria—leading the pathologist occasionally to describe them as undifferentiated cancers.

Special-staining reactions may or may not reveal the ability of these tumors to reduce ammoniacal silver salts. This special staining technic is highly useful when the result is positive, but a negative result does not necessarily exclude the diagnosis of carcinoid. The argentaffin granules are thought by some to represent artifacts produced by the chemical fixation, and actually to be serotonin. Morson[4] explains the failure to demonstrate these argentaffin granules by stating that tumors without them have arisen from Kultschitsky's (argentaffin) cells before these elements have achieved the ability to produce granules.

Carcinoids, as the name implies, are potentially malignant lesions. Bates,[13] in an excellent review of the subject, reported that the carcinoid lesions that are less than 1.0 cm in cross diameter are rarely clinically malignant; whereas, of those more than 2.0 cm in greatest diameter, approximately from 75 to 80 percent give rise to metastasis. Of the lesions that are less than 2.0 cm in diameter and which are malignant, most penetrate into the muscularis propria.

Men are slightly more commonly affected than women, and the peak instance for these lesions is the sixth decade for men and the fourth decade for women. In Bates'[13] series, most of the benign lesions were present in the

middle third of the rectum on the anterior wall; whereas most of the malignant lesions were annular and occurred in the lower two thirds of the rectum.

Summary

These four different types of colonic polyps are especially important because they present little chance of lethal malignant disease. They are best managed by local treatment.

Large or annular lesions usually require resection. Carcinoids less than 1.0 cm in diameter should be removed by local excision. The tumor must be removed without cutting into it, for implantation of tumor cells can occur, especially when sutures are required. Electrosurgical methods of excision minimize the possibility of implantation.

Early Follies

The demarcation between the legitimate physician and the quack was shadowy during the eighteenth century and for some time to come, because of the tenuous basis of the former's theory and practice. Thomas Percival could write with great justification in 1777:

"A list of all the follies which at different times have been established as articles of faith in medicine, would form the severest satire on the healing art. Who can withhold his laughter when he reads of expelling, attracting, and concocting faculties; of energies, sympathies, antipathies, idiosyncrasies, and occult causes; of the body being nothing but salt, sulphur, and mercury; of man being a microcosm, and uniting in his frame the motion of the stars, the nature of the earth, of water, air, all vegetables and minerals, the constellations, and the four winds. Yet ridiculous as these several tenets may appear, they have given rise to sects, have been espoused with warmth, and defended with acrimony."

At that time the "animism" of Stahl, the "aether" of Hoffman, the "solidism" of Cullen, the "iatrochemical' and "iatro-physical" and "Old Vienna" schools were popular in different medical circles, while the less speculative work of Harvey and Sydenham had hard sledding.*

*Bernhard Stern: Society and Medical Progress, 1941.

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

Ovulen-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

works the way a woman thinks

by weekdays...not "cycle days"

Whether it be "shopping day," "bridge day" or "housecleaning day," a woman is accustomed to thinking in terms of days of the week rather than in "cycle days." Ovulen-21 lets her remember her natural way. Once established, her starting day is always the same day of the week... because it is fixed at three weeks on — one week off and is independent of withdrawal flow.

The same Ovulen in the same low dosage... with the same low incidence of side effects and the same high degree of protection against pregnancy.

Note: Ovulen remains available in the familiar round Compack for those women who may wish to continue to use the traditional 20-day schedule. Be sure to specify Ovulen-21 to assure each new patient of the advantages of the new *Three Weeks On—One Week Off* schedule. She might appreciate your budget-minded authorization for a six-month supply (five Refills).

Indication — For oral contraception.

Contraindications — Thrombophlebitis or a history of thrombophlebitis or pulmonary embolism, liver dysfunction or disease, known or suspected carcinoma of the breasts or genital organs and undiagnosed vaginal bleeding.

Warnings — Discontinue medication pending examination if sudden partial or complete loss of vision, or sudden onset of proptosis, diplopia or migraine occurs. Discontinue if papilledema or retinal vascular lesions occur. Since the safety of Ovulen in pregnancy has not been established, rule out pregnancy before a patient who has missed two consecutive menstrual periods continues the tablets. Consider the possibility of pregnancy at the first missed withdrawal flow if the recommended schedule has not been followed. The active ingredients in oral contraceptives have been identified in the milk of mothers receiving these drugs. The significance of this to the infant has not been determined.

Precautions — The pretreatment physical examination should specifically include the breasts, pelvic organs and a Papanicolaou smear. Endocrine and possibly liver function tests may be affected by Ovulen. Such tests should be repeated two months after stopping the medication if their results were abnormal in a woman taking Ovulen. Pre-existing fibroids may enlarge under the influence of progestin-estrogen preparations. Patients with epilepsy, migraine, asthma, cardiac or renal dysfunction, which conditions might be influenced, require careful observation because Ovulen may cause some degree of fluid retention.

Ovulen should be used with caution in patients with a history of cerebrovascular accident. Nonfunctional causes should be considered if breakthrough bleeding occurs. Adequate diagnostic measures are indicated in women with undiagnosed vaginal bleeding. Carefully observe patients with a history of psychic depression and discontinue the medication if depression recurs to a serious degree. Any possible influence of prolonged Ovulen use on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. Carefully observe diabetic patients during Ovulen use since a decrease in glucose tolerance has occurred in a few such patients. Physicians should be alert to the earliest manifestations of thrombophlebitis and pulmonary embolism since such conditions occasionally occur in patients taking oral contraceptives. Use Ovulen judiciously in young patients in whom bone growth is not complete because of the effects of estrogens on epiphyseal closure. Age is no absolute limiting factor, although Ovulen use may mask the onset of the climacteric. Pathologists should be informed of Ovulen use when relevant specimens are submitted.

Side effects — The following adverse reactions have been observed in varying incidence in patients taking oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma or melasma, breast changes (tenderness, enlargement, secretion), change in weight (increase or decrease), changes in cervical erosions and secretions, suppression of lactation when used immediately post partum, cholestatic jaundice, migraine, allergic rash, rise in blood pressure in susceptible individuals and mental depression.

Although the following side effects have been reported in users of oral contraceptives no cause and effect relationship has been established: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme and nodosum, hemorrhagic eruption and itching. Thrombophlebitis, pulmonary embolism and neuro-ocular lesions have occurred in users of oral contraceptives, although a cause and effect relationship has been neither established nor disproved.

The following laboratory results may be altered by oral contraceptives: Bromsulphalein® and other hepatic function tests—increased; coagulation tests, including prothrombin, Factors VII, VIII, IX and X — increased; thyroid function — increase in protein-bound iodine and butanol extractable protein-bound iodine, and a decrease in T^3 values; metyrapone test and pregnanediol determinations.

Dosage and administration — One tablet of Ovulen-21 daily for 21 consecutive days, beginning five days after the onset of a menstrual flow (the first day of menstruation is counted as day 1), then discontinued for one week. If Ovulen is started later than day 5 after menses begins another method of protection is used until the first seven tablets have been taken. Subsequent 21-day courses are begun on the eighth day after the last tablet was taken in the preceding cycle. This three weeks on — one week off schedule is continued whether or not withdrawal flow has begun, flow has ceased or spotting or breakthrough bleeding has been experienced.

If one tablet is missed it is to be taken as soon as it is remembered and the next tablet at the usual time. If two consecutive tablets are missed the dosage is doubled for the next two days, then the regular schedule is resumed. If three consecutive tablets are missed a new tablet cycle is started on the eighth day after the last tablet was taken. For the best protection in the latter two instances instruct the patient to use another method of contraception until the next seven consecutive tablets have been taken. The possibility of ovulation increases with each successive tablet missed.

Postpartum administration — Non-nursing mothers may begin Ovulen immediately after delivery and nursing mothers after lactation is well established.

Ovulen-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

three weeks on...one week off

In the complex picture of moderate to severe anxiety...

there is a new reason for prescribing Mellaril (Thioridazine HCl)

effectiveness in mixed anxiety-depression

Long recognized for its usefulness in the treatment of moderate to severe anxiety, Mellaril is now also known to be effective against mixed anxiety-depression.

Often the symptoms of anxiety states are difficult to sort out—even with the most careful probing. The patient may manifest symptoms of agitation, restlessness, insomnia, somatic complaints. But what of the depression that may be mixed in the total picture? It is reassuring to know that Mellaril may be prescribed—with strong possibilities of success—when there is anxiety alone or a mixture of anxiety and depression.

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine hydrochloride). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

Mellaril®
(Thioridazine HCl) 25 mg. t.i.d.

for moderate to severe anxiety and mixed anxiety-depression

Minnesota Medicine and the Cleveland Clinic

SPECIAL ISSUES of a journal from one institution have, I believe, the chief merit of giving the reader a sample of its flavor. Often quite unconsciously such an issue betrays the collective interests of the staff, and it is the staff that is the core and consciousness of an organization.

Over the past 28 years I have watched and participated in the slow change in character of the Cleveland Clinic. I suspect I entered the institution during the demise of an era—an era characterized by vigorous and highly skillful surgery, a make-do era as regards physical equipment and plant, an era of one-man rule in each bailiwick, an era when research was for second-class citizens, and an era when public funds were anathema. The volume of surgery did not increase proportionately to that of medicine with the passing of time, thanks to increasing use of antimicrobial agents and increasing understanding of the mechanisms of disease. Psychiatry became acceptable and rehabilitation of the physical plant began; leaded glass windows were replaced by sealed-in windows and air conditioning.

But intellectually, the two greatest changes were the hectic growth of research in cardiovascular disease and its application, and the diffusion of responsibility to the younger staff. It has been said somewhat cynically that in big institutions, Peter's principle applies, i.e., each employee tends to rise to his level of incompetence. Thus, in theory, employees are promoted until they reach a position for which they are incompetent, and there they stay. This, of course, is in the main untrue. A broader spectrum of responsibility in the young institutional physician, in my opinion, makes him grow up sooner. The only real loss in diffusion of authority is twofold: (1) some of the discipline of the physician's life in relation to his patients and the institution may vanish, and (2) there is too little concentrated authority for a leader to make sensible exceptions to general rules. This latter trend inevitably makes duplication of people quite as rapid as the Xerox machine makes of reports.

When I look back, I look forward with the greater satisfaction. The younger generation may not be as erudite as we are, but it is amazing how fast they learn so much more than we ever will. I commend the contents of this issue of MINNESOTA MEDICINE to the reader as proof of this contention.

Irvine H. Page, M.D.*
Cleveland, Ohio

*Director Emeritus, Research Division of The Cleveland Clinic Foundation.

What can be done for Susan Jane To stop the runs and crampy pain?

Parepectolin for quick relief of acute diarrhea
...soothes colicky pain with paregoric
...consolidates fluid stools with pectin
...adsorbs irritants with kaolin, and protects intestinal mucosa.

In children, Parepectolin may be used to control diarrhea promptly and prevent dehydration, until etiology has been determined. In some cases, Parepectolin may be all the therapy necessary.

Parepectolin®

Each fluid ounce of creamy white suspension contains:
Paregoric (equivalent) ..... (1.0 dram) 3.7 ml.
Contains opium (¼ grain) 15 mg. per fluid ounce.
warning: may be habit forming
Pectin ..... (2½ grains) 162 mg.
Kaolin (specially purified) .... (85 grains) 5.5 Gm.
(alcohol 0.69%)
Usual Children's Dose: One or two teaspoonfuls three times daily.

The Editors of MINNESOTA MEDICINE

WITH THIS issue MINNESOTA MEDICINE is privileged to publish a significant group of papers from the Cleveland Clinic, which ranks among the great private medical institutions in the world providing service unstintingly to all who seek it. As one would expect in this country of medical free enterprise, such a concentration of medical talent in one institution promotes special studies of unusual diseases and treatment not practicable in a smaller institution. The Cleveland Clinic's kidney dialysis and cardiac units represent a contribution to medicine which would be impossible under the intricacies of a bureaucratic system.

The Board of Editors of MINNESOTA MEDICINE thank the Cleveland Clinic for their papers in this issue. We invite this Clinic and other medical organizations, who might wish to present their material to physicians, to publish again in future issues of MINNESOTA MEDICINE.

Problems in Health Care

THE PAST 25 years of my life have been very interesting, albeit strenuous, for they mark a time when I have been acutely conscious of strife about the practice of medicine. Many physicians, especially the younger but not exclusively they, will find it astonishing that the situation that troubles all of us in medicine has existed so long.

When in the 40's a National Health System was proposed in Congress, the annual national expenditure for health was $8 billion. We then pondered what effect this legislation would have on future expenditures for medical care and predicted direly that it might go as high as $15 billion. Almost everyone knows the amount has now risen to $40 to $50 billion, without a National Health System, reflecting the will of the people to put this much of their income into health care.

More recently the Congress decided to inject approximately $5 billion into the health care industry. This action has satisfied some demands but at the same time has created a great deal of dissatisfaction and unrest in a system which, while far from perfect, is quietly doing the work. In many respects our progress has been spectacular. One bit of supporting evidence is that the United States has become the center of the world's interest in medical affairs.

An important development during this 25-year period is that population shifts have upset the distribution of health care to people as they congregated here and dissipated their numbers there. Thus pockets of concentrated need and open spaces of widely dispersed demand were created without any apparent substitute to take the place of the former cozy relationship of a relatively small unit of population with its own physician or "doctor."

Another problem is that of financing health care. Subsidizing the care of the medically indigent requires expenditures locally and nationally that are shocking to contemplate. Paying agencies react by suggesting controls, stricter definitions of eligibility for benefits and arbitrary regulation of the prices paid for units of service. Perhaps we should recognize these actions as evidence of fiscal responsibility to be preferred to the roseate promises of free care. Regulations and guidelines are not perfect and require development. The providers' understanding is needed to make them equitable and just.

Distribution of services is related to such characteristics as numbers, availability, effi-

Morton Salt introduces will power in a shaker

You probably know how hard it is for your patients to stay on a low-sodium diet. They try, but simply can't cut out salt completely. Now there's a product that's far more dependable than will power: New Morton Half/Salt Mixture™.

It contains half the sodium of table salt but gives your patients all the satisfaction of true salt flavor. If your patients think low-sodium diets are hard to swallow, let them use new Morton Half/Salt Mixture. It's a happy compromise.

ciency, and a quality of effectiveness. Much service demand we know is elective. Looking at the supply end we tend to blame someone for insufficient numbers of health workers. While we must continue our efforts to educate and train more physicians, nurses and allied personnel, we also should acknowledge that there are finite limits to the education system. Consequently more consideration should be given to the efficient use of our available resources. Ordinarily in medicine, crash programs are neither practical nor successful. The evolutionary approach will serve us still if we are alert.

It is often said that health service providers are not readily available at all times. Actually this laudable objective can only be approximated. I do not find it astonishing, when one considers the size of our country, that someone sometime will suffer an emergency unattended. However, the occasion still is so infrequent as to attract front page attention. I do not find it strange that health workers might seek relief from a 168-hour week. As they see their fellow citizens enjoying leisure and recreation, providers should be expected to yearn for some of these same pleasures. It is not a lack of devotion so much as a need for a plan for substitution or replacement. Proper planning will solve many of our difficulties.

There is a lot of work to be done to improve our situation. Unless one wants to be pedantic there is no crisis; but there is no room for complacency, either. We must provide new forms of organization for delivering health services and devise ways to make the financing of health care reasonable. This is our charge. We must keep working at it.

Charles L. Hudson, M.D.*
Chicago, Illinois

*Director Division of Health, Service, American Medical Association, Chicago, Illinois. Former staff member, Cleveland Clinic, Cleveland, Ohio.

The Computer Versus the Clinician

THERE IS A temptation to believe, in this electronic era, that the practice of medicine in the future will be so systematized that only facts need to be fed into a properly programmed computer, and out will pop, within a matter of seconds, the correct diagnosis and details of management for the particular disorder from which a patient suffers. Alas, this 'ideal' type of armchair medicine can never come to pass, merely because computers are only as clever as the human beings who program them, and no more accurate than the human beings who feed in the data. No amount of computerized data will bring the patient to a breast biopsy if the examining physician has not felt the suspicious lump. No computer interpreting an electrocardiogram will be a substitute for the physician who is evaluating the patient with sudden chest pain and is able to observe the manifold evidences of a grave situation whose multiple components can hardly be recorded rapidly in specific measurements.

The mechanization of laboratory procedures which makes available a vast amount of laboratory information, at a nominal expense, constitutes a clear and abiding danger to the training of the young physician. The temptation will be for him to look at the laboratory reports instead of at the patient. Yet every clinician ought to have a deep distrust of laboratory data that appear to run counter to his clinical evaluation of the patient. The "S.M.A. 12" is an example of a multichannel screening device that will give determinations for twelve selected blood elements from a single blood sample. It represents a significant contribution to medical care and is an inexpensive extension of the routine blood count, urinalysis, and roentgenogram of the chest which have been a part of every complete medical examination for a great many years. Accurate information is never potentially dangerous or unwelcome (although it may be unessential), but no series of laboratory tests can give results that do more than indicate a lead to the clinician.

It is unfashionable these days to stress the importance of accurate and pertinent history taking, accurate observations of physical find-

HOW TO TURN YOUR RECEPTIONIST INTO AN INSTANT INFORMATION RETRIEVER

You have a problem: no matter how faithfully you read your professional journals, you still waste hours tracking down the article you need now.

Forget it!

New Instadex frees you from searching out key reference information. In seconds your receptionist can hand you summaries of all the right articles from every journal you follow. You can then go straight to the article that interests you and spend your time reading instead of searching.

Instadex was developed by a practicing internist who discovered—just as you have—that he was spending too much time hunting down half-remembered reports. Based on *Index Medicus'* subject analysis, this new system is so completely cross-indexed you cannot miss finding the article you want.

What's more, Instadex reaches you ready for immediate use. *You* do no processing or arranging. Instadex requires *no* filing. (Your girls will bless you for that!) In fact, Instadex supplements or completely replaces whatever card file you now maintain.

In mere seconds your receptionist hands you every reference in your file on the Guillain-Barre' syndrome.

If the Instadex system saves you just four hours a *year* it will have paid for itself! We'll bet it'll save you four hours a month . . . or even more.

Ask your receptionist to write today for detailed information and prices. Why waste time fishing for information when you've other fish to fry?

The Editor's Soliloquy

Like A Broken Record—The Popular Monologue

THIS ISSUE OF MINNESOTA MEDICINE is an example of the free interchange of new ideas between competing medical groups, all of whom are striving for betterment of the health of its people. In any other profession new and original ideas are secretly guarded or "protected" with copyrights* and "patents pending." To a worthy contemporary we extend our salute!

Our modern age abounds in paradoxes!

In this, the one country of the world where medical science has prospered and progressed, it has become popular to decry the medical profession for allegedly disregarding the ills of the majority because a few isolated individuals who are in need of attention will not seek out the medical aid available to them.

Rather than disparagement our American medical fraternity and its allied professions should be credited with having advanced medicine from a handful of simple specifics to thousands of life-saving drugs and procedures. True, the cost has been high; but the acceleration rate of improvement has been exponential compared with that of other types of service.*

To be sure, it is only a small but vociferous minority who constantly bark this monologue about medicine's omissions; yet they themselves usually constitute the very group who are averse to betaking themselves to the nearest center where the highest grade of medical science and technology is available without charge if the need exists. Can they be so irrational and unreasonable as to expect sophisticated and expert medical service to be available to anyone at any time at every Toonerville and crossroads where little more than first aid can be provided? Backwoods medicine and kitchen-table surgery are features of the nostalgic past: relics of frontier emergency and make-do. That frontier has now vanished; the horse-back doctor will never return. With modern speedy transportation it is far more feasible for the patient to proceed to the nearest medical center than for the doctor to go to the patient. But does the caviler blame himself for his failure to bestir himself? No indeed! He faults the medical profession, the caste system, the political establishment, the social order: any scapegoat will do!

Countries that have instituted socialized medicine have fallen far behind in medical progress; yet they cannot extricate themselves from a dilemma that has eventuated in excessive cost and inefficiency. They find their doctors padding their accounts with 40 to 50 house calls and 80 to 90 office visits daily, aggregating as many documentary blue slips to be turned in to their government for "services rendered" from patients visiting the doctor for the most part simply because of the human penchant to avail themselves of "free" service with a "bonus" of a box of tinted pills or a bottle of colored medicine posessing no more than placebo value.

Is our professional competence to be prostituted, our dedication depreciated, our independence from beadledom abnegated, our integrity stultified by a program that does not show our talents? Must we continue to administer our skill, give generously of our time and energy, maintain our equanimity, extend our compassion in the face of criticism and harassment by malcontents, who pressure to have the utopian solution for every social malady?

The day may well come when the distinguished medical profession in this country will unanimously and unequivocally repudiate the nefarious charge of medical inadequacy and inequity and insist on their prerogative of providing medical care in one way only: their own manifestly knowledgeable way.

Carl O. Rice, M.D.

Curbstone Consultation

Anorexia Nervosa

QUESTION: Is anorexia nervosa a single entity or does that diagnosis imply a more serious psychiatric problem such as schizophrenia? Do these children ever get completely well?

ANSWER: There are many variations of anorexia nervosa, but with weight loss, amenorrhea, excessive exercise, dieting, vomiting, and above all, an unconscious and sometimes conscious rejection of adult femininity (or rarely masculinity), I should call it a discrete entity. Quite often these individuals become schizophrenic, but as likely as not they are severely obsessive-compulsive persons. They can get "completely well," but it does not happen often.

Richard B. Markey, M.D.*
Cleveland, Ohio

*Department of Psychiatry, The Cleveland Clinic Foundation, Cleveland, Ohio.

'Living Virus'

QUESTION: Would you comment on Doctor Kornberg's synthesis of a 'living virus'? Do you really think there is a possibility of changing the genetic structure of human lungs?

ANSWER: There is no doubt that Doctor Kornberg's synthesis of an active, disease-producing virus represents a major landmark in the history of medical research. However, since the "living" nature of viruses is still controversial, and since his synthesis required the presence of an active, naturally occurring enzyme, it should not be construed as the first "test-tube" synthesis of life. Doctor Kornberg himself has emphasized this point. The major significance of his work is that it opens the possibilities to enable man, some day, to induce genetic alterations at will. The potential applications of such a procedure in the practice of medicine would be limitless.

Sharad Deodhar, M.D., Ph.D.*
Cleveland, Ohio

*Division of Pathology, The Cleveland Clinic Foundation, Cleveland, Ohio.

Inactivated Measles Vaccine

QUESTION: What is the concern about the use of inactivated measles vaccine and why has the Committee on Control of Infectious Diseases of the American Academy of Pediatrics advised it be discontinued?

ANSWER: Unusual systemic reactions have been noted in patients who have come into contact with natural measles when they have previously received the inactivated vaccine. Also, in some of these persons receiving live attenuated vaccine, after previous exposure to the inactivated vaccine, a local reaction has been seen at the site of the injection. Reactions of this sort have not been observed in persons who have received only the live vaccine.

Derrick Lonsdale, M.D.*
Cleveland, Ohio

*Department of Pediatrics, The Cleveland Clinic Foundation, Cleveland, Ohio.

Ulcerative Colitis and Emotional Disturbance

QUESTION: What are the present thoughts concerning the relationship of ulcerative colitis and emotional disturbances? Is an emotional disorder the cause of ulcerative colitis?

ANSWER: The etiology of ulcerative colitis remains unknown. The association of emotional problems in some children with ulcerative colitis is noted, but, in others, obvious emotional conflicts are absent. Attempts to treat the family emotional conflicts as the primary therapy of the child with ulcerative colitis have not resulted in medical improvement of the child. In fact, in the initial therapy of the child with ulcerative colitis, if emotional causes of the disease are openly alluded to, the physician may actually hinder his ability to treat the child. Until more is known regarding the etiology of this disease, the medical therapy of the child with ulcerative colitis must be flexible and focused on treating the whole child.

William M. Michener, M.D., M.S.(Pediatrics)*
Albuquerque, New Mexico

*Formerly member of the staff, Department of Pediatrics, Cleveland Clinic; present address: University of New Mexico Medical Center, Albuquerque, New Mexico.

Early Active Rheumatoid Arthritis

QUESTION: How do you manage patients with early active rheumatoid arthritis who respond satisfactorily to treatment except for persistent pain and swelling of ankles?

ANSWER: This condition is usually due to chronic foot strain resulting from a flexible or depressed longitudinal arch, which in turn causes tenosynovitis of the tibial and peroneal tendon sheaths. Treatment is directed toward elimination of mechanical stress forces on the involved tendons. Well-fitting shoes with adequate arch supports should be worn at all times. Heel and sole wedges are used when indicated. Walking barefoot or in soft slippers is discouraged. Daily physical therapy, including contrast baths and foot and leg exercises and correct posture in standing and walking, is emphasized. These patients should avoid standing or walking for long periods, and weight reduction is prescribed when indicated. It is important to advise these patients to carry on with proper foot care indefinitely, in addition to any other therapeutic measures that are used.

Arthur L. Scherbel, M.D.*
Cleveland, Ohio

*Department of Rheumatic Disease, The Cleveland Clinic Foundation, Cleveland, Ohio.

Infected Intervertebral Disk

QUESTION: What are the diagnostic features of an infected intervertebral disk?

ANSWER: One must be suspicious of a disk infection in any patient with severe back pain accompanied by frequent incapacitating episodes of muscle spasms affecting the back, legs, and even the abdomen. Precipitation of the episode by even the slightest jarring has led to the use of the "bed-jarring" test. The attacks are so dramatic that these patients are often thought to be hysterical. The history of recent systemic infection, especially urinary, is often obtained. Frequently there has been some type of spinal or paraspinal needling in the recent past. Unfortunately, changes caused by infection are usually not apparent roentgenographically for from six to eight weeks. The sedimentation rate is increased in most patients, but the leukocyte and differential counts usually are normal.

Disease as Reprisal

What threats of horrendous retribution did the Lord make to those who might fail to keep his covenant?

The Lord shall make the pestilence cleave unto thee, until he have consumed thee from off the land, whither thou goest to possess it.

The Lord shall smite thee with a consumption, and with a fever, and with an inflammation, and with an extreme burning, and with the sword, and with blasting, and with mildew; and they shall pursue thee until thou perish.

The Lord shall smite thee with the botch* of Egypt, and with the emerods†, and with the scab, and with the itch, whereof thou canst not be healed.

The Lord shall smite thee with madness, and blindness, and astonishment of heart.

The Lord shall smite thee in the knees, and in the legs, with a sore botch that cannot be healed, from the sole of thy foot unto the top of thy head.

Then the Lord will make thy plagues wonderful, and the plagues of thy seed, even great plagues, and of long continuance, and sore sicknesses, and of long continuance.

Moreover he will bring upon thee all the diseases of Egypt, which thou wast afraid of; and they shall cleave unto thee.

Also every sickness, and every plague, which is not written in the book of this law, them will the Lord bring upon thee, until thou be destroyed. (Deuteronomy 28:21, 22, 27, 28, 35, 59-61)

*Botch—sores
†Emerods—hemorrhoids

DERIVATIVELY SPEAKING

Nidus—from Latin *nidus* (a nest).

A wise man knows everything; a shrewd one, everybody.—Anonymous

To help you manage hypertensive patients:

Initiate therapy with **Hydromox*** Quinethazone 100 mg. (two 50 mg. tablets) daily for 15 days

Many patients with hypertension may obtain the greatest benefit from HYDROMOX Quinethazone when it is given in a single daily a.m. dose of 100 mg. (two 50 mg. tablets). This dosage effectively reduces systolic and diastolic pressure, and reduces edema when present. We suggest continuing clinical evaluation over a 15-day period of therapy. If results are satisfactory, a reduction to 50 mg. (1 tablet) daily will usually be adequate for maintenance.

Precautions: Electrolyte abnormalities may be aggravated or produced. Caution is important during prolonged or intensive therapy and when salt intake is restricted. Hypokalemia has been mild and infrequent, and other electrolyte abnormalities rare. The possibility of potassium depletion and its toxic sequelae must be kept in mind, particularly in cirrhotics and patients receiving digitalis. As a preventive measure the use of foods rich in potassium, such as orange juice, may be desirable. Although not a thiazide, HYDROMOX may possess certain characteristics of the thiazides. They have been known to cause jaundice with liver involvement and pancreatitis; hematological complications such as purpura with or without thrombocytopenia and leukopenia (neutropenia); increases of serum uric acid; decreased glucose tolerance as evidenced by hyperglycemia and glycosuria thus aggravating or provoking diabetes mellitus and azotemia in patients with renal disease: photoallergy. Discontinue use a few days prior to elective surgery. When added to a regimen that includes ganglionic-blocking agents, the dosage of these latter preparations should be reduced. Also reduce dosage when one or more of these antihypertensive agents is added to an established HYDROMOX regimen. Contraindicated in anuria. Observe for possible hematologic complications.
Side Effects: Skin rash; gastrointestinal disturbances (chiefly nausea), weakness, dizziness. These seldom require cessation of therapy, and can be relieved by reducing dosage or correcting electrolyte imbalance.
Warning: Enteric coated potassium tablets have been implicated in small bowel lesions and should be used only when adequate dietary supplementation is not practical.

Fracture-Trauma Conference

The Patient with Multiple Fractures

THE PRESENT epidemic of trauma—especially from auto accidents— has increased the importance of the management of patients with multiple injuries. This fracture trauma conference illustrates the principles involved in the care of the severely injured patient, including the treatment of hemorrhagic shock and the management of open fractures.

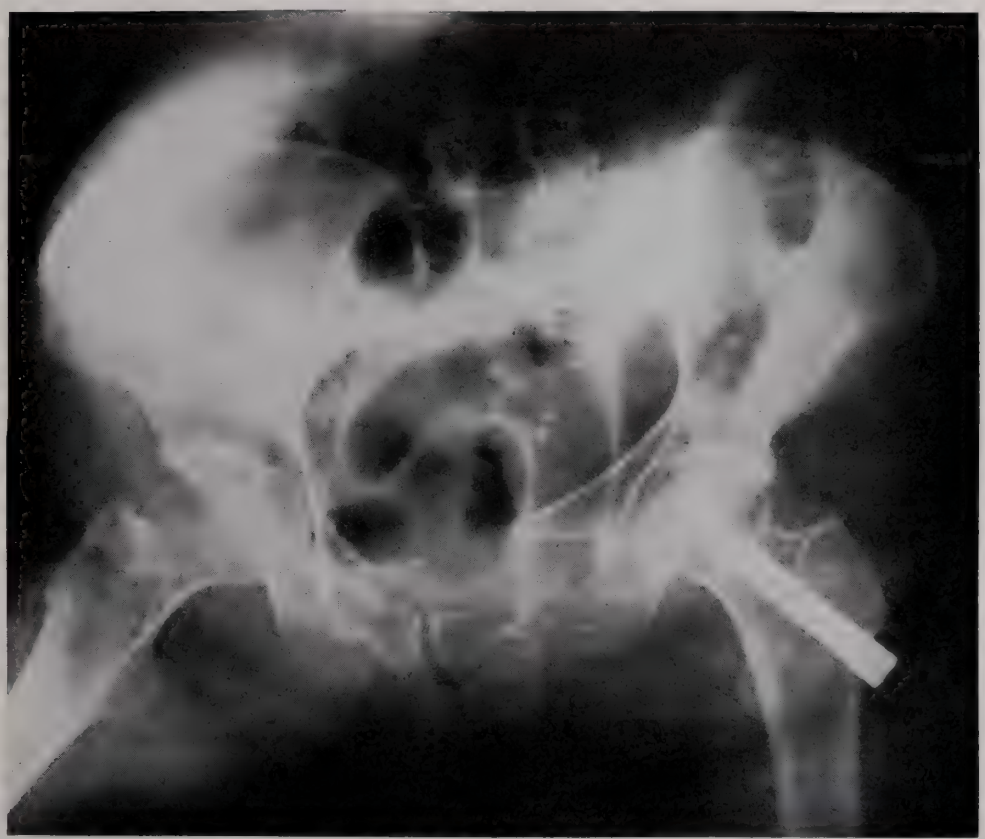

Fig. 1—Fractures of superior and inferior pubic rami bilaterally, subluxation of left sacroiliac joint.

Dr. Karl S. Alfred:* **Case History**

On the evening of March 3, 1967, a 79-year-old Caucasian seamstress for a dry cleaning company was brought to the emergency room of St. Vincent Charity Hospital with a large compound wound of the inner aspect of the left thigh and with several inches of femur protruding from the wound. The patient was fully conscious, and stated that she had been struck by an automobile while waiting for a bus and that the vehicle had run over both her legs. She had just left a church service and was standing at the bus stop when she was struck. The accident occurred just a few blocks from the central police station and the patient was brought to the hospital by police ambulance within minutes from the time of the accident. She had pain in both legs and the lower part of the abdomen. As stated above, there was a large wound of the inner aspect of the left thigh with 3 or 4 inches of the proximal left femur protruding. There was tenderness over the groins and the lower aspect of the right thigh. The blood pressure was 156/110 mm Hg, pulse rate 112, blood hemoglobin content, 12.1 g per 100 ml, hematocrit 39, and a catheterized urine specimen was clear. Anti-gas-gangrene and tetanus medication was administered immediately, as well as 1 g of streptomycin and 2,000,000 units of penicillin. Roentgenograms of the chest, abdomen, pelvis, and both thighs were obtained; these revealed multiple fractures of the pelvis with subluxation of the left sacroiliac joint and an old healed fracture of the neck of the left femur, with the Smith-Petersen nail still in place (Figure 1). Figure 2 shows the compound fracture of the left femur with displacement of the proximal fragment and its exit through a large medial thigh wound. Figure 3 reveals a fracture of the right medial femoral condyle in good position.

Evaluation of the patient's condition resulted in the decision to operate on the large compound bleeding wound of the left femur. The patient was typed for blood and cross-matched, and an infusion of a unit of dextran was started in the emergency room. In the operating room the blood pressure was imperceptible, and the pulse weak though fairly constant. With the anesthesiologist and surgical team observing the patient and treating the shock, she began

*Chief of Orthopedic Department, St. Vincent Charity Hospital, Cleveland, Ohio.

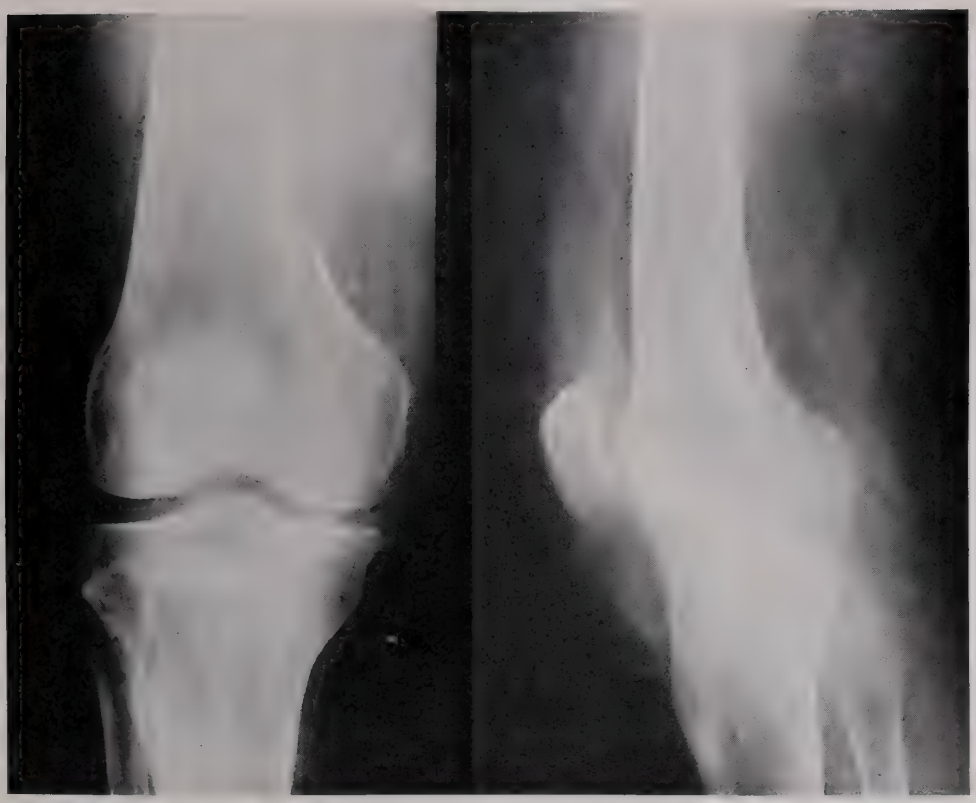

Fig. 3—Fracture of right medial femoral condyle with minimal displacement.

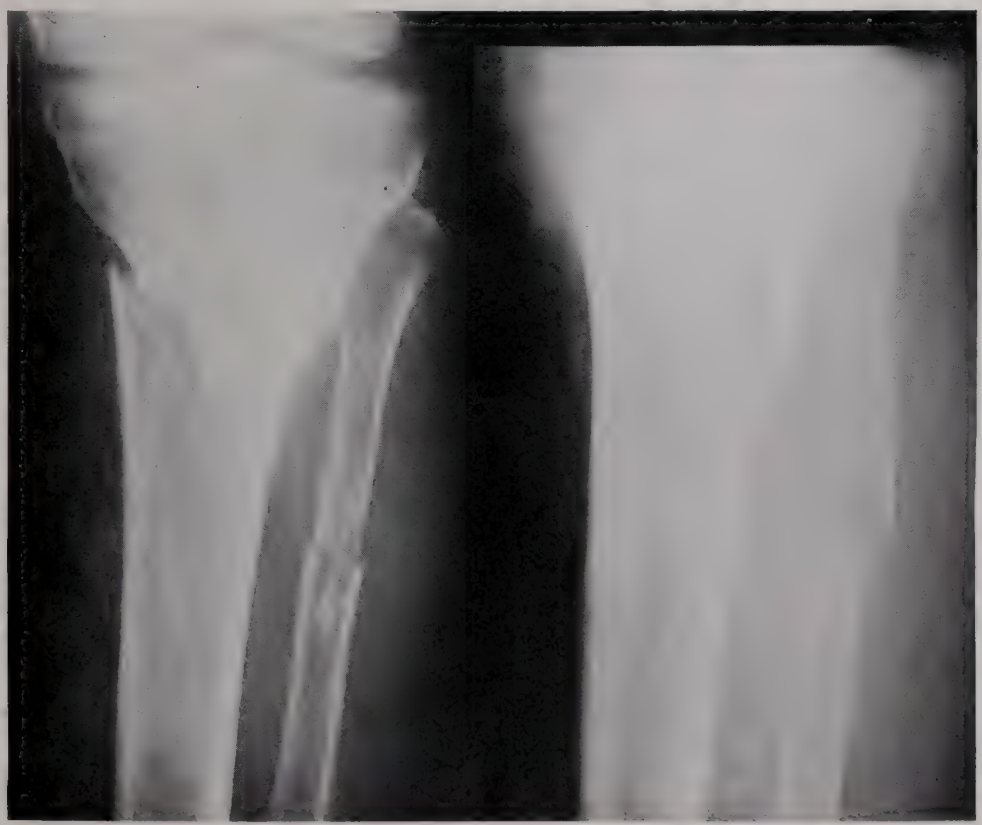

Fig. 4—Fracture of proximal portion of left tibia and fibula.

to rally after a second unit of dextran and the administration of whole blood. When the blood pressure stabilized at 120/80 mm Hg, and the pulse became full and regular, definitive treatment was considered. Several units of blood were in readiness, and the patient's status was considered sufficiently satisfactory for administration of a general anesthetic and a short surgical procedure, provided it would not add too much more trauma. Under general anesthesia the patient's condition remained stable. The left thigh revealed a large laceration of the skin and subcutaneous tissues, and the proximal femur protruding through a large wound in the vastus medialis and adductor muscles. After superficial wound debridement and irrigation, the patient's condition was still stable. Further exploration revealed that the distal femoral fragment was easily accessible in the deeper aspects of the wound; both fragments could easily be grasped with bone-holding forceps. Despite the presence of the nail in the neck of the left femur it was decided that it would be feasible to stabilize the femur with an intramedullary nail, with the only further trauma being a small stab wound to remove the nail, and the retrograde incision above the hip for the intramedullary nailing. The Smith-Petersen nail was easily removed with a Kocher clamp by palpation through a 1-inch incision, and a Schneider intramedullary nail was driven into the proximal fragment and then into the distal fragment without further dissection. Fixation was excellent and the wounds were closed primarily. At the conclusion of the procedure the patient had received two units of dextran, three units of blood, and her blood pressure was 130/90 mm Hg. At this time, with the left femur stabilized, crepitus was palpable and abnormal motion demonstrable just below the left knee. Roentgenograms revealed a fracture of the proximal portion of the left tibia and fibula (Figure 4). Massive long-leg "soft casts" were applied, and the patient was in good condition when she left the operating room. She received a fourth unit of blood in the intensive care unit and a total of 1000 ml of lactated Ringer's solution, and 500 ml of 5% dextrose in ¼% normal saline solution. The blood pressure remained stable around 100/70 mm Hg all night.

The next day the blood hemoglobin content was 9 g per 100 ml. hematocrit 25, pulse rate 72, respirations 20; and the blood pressure fell to 90/60 mm Hg. She was given another unit of blood in addition to other supportive measures. The urine output decreased to 50 ml in eight hours, and the blood urea nitrogen (BUN) was 27 units. She was given mannitol, and the urine output increased to 90 ml per hour. Urine output remained good and the BUN decreased. During the next five days, after a further decrease in hemoglobin content to 8.5 g per 100 ml, she was given five more units of blood, and on March 9, 1967, six days after the injury, her hemoglobin content was 12.1 g per 100 ml, and the hematocrit 36. She had received a total of 10 units of whole blood and her condition was good. Figure 5 shows the position of the pelvic fractures at that time, and Figure 6, the left femoral shaft fracture.

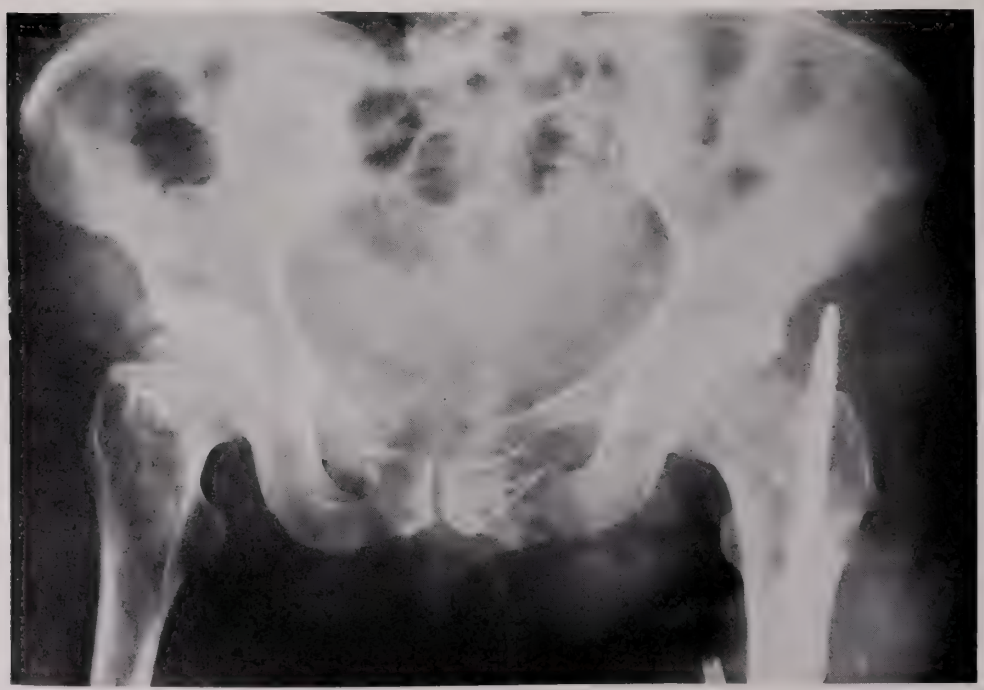

Fig. 5—Postoperative view of pelvis and proximal portion of Schneider nail in left femur.

After the initial doses of streptomycin and penicillin, she was treated with erythromycin and then chloromycetin. The temperature curve was persistently elevated, but the leukocyte count remained low and there were no signs of infection. Vomiting and diarrhea developed, and medical consultation was obtained on March 16, 1967. No definite cause for the fever or the vomiting and diarrhea could be determined, but medication was changed to mystatin which was maintained from March 17 to March 23, 1967; and thereafter she was given amphocillin q.i.d. from March 27 to March 30, 1967. The symptoms subsided. On March 27, 1967, about three and one-half weeks after the injury, she was given a general anesthetic, and posterior plaster splints were applied with massive compression bandages. The left thigh wound and the surgical wounds about the left hip had healed per primum. She had a superficial sacral pressure sore and also severe excoriation of the perineum, both of which lesions cleared under local treatment with alum and heat. There were massive ecchymoses of the buttocks and pelvis, but with no skin lesions. The plaster leg splints were applied so that the patient could be mobilized, and on March 31, 1967, four weeks after the injury, she sat in a chair for the first time. Figure 7 shows the position of the left tibia and fibula fracture in a posterior plaster splint.

For the next two weeks the patient continued to improve, but then again developed a temperature elevation and pain in the right lower abdominal quadrant, with localized tenderness. On April 18, 1967, exploratory operation over the right lower quadrant revealed only sterile

Fig. 6—Excellent position of left femoral shaft fracture with intramedullary fixation.

amber fluid. Cultures of the fluid were negative. There was no intraabdominal pathology. The patient's condition improved, and on April 25, 1967, the right leg cast was removed and she was started on physiotherapy, with progressive weight-bearing on the right leg on the next day. On April 28, 1967, the left leg splint was removed and physiotherapy was continued with progressive weight-bearing on both legs. The patient had spent her eightieth birthday in the hospital and she was discharged on May 24 1967, ambulatory and in good condition. Figures 8, 9, and 10 show that the fractures of the pelvis, left femur, left tibia and fibula, and right medial femoral condyle had healed well after nine months. The Schneider nail was removed on January 8, 1968. Despite her multiple severe injuries and her 80 years the patient intended to return to work as a seamstress.

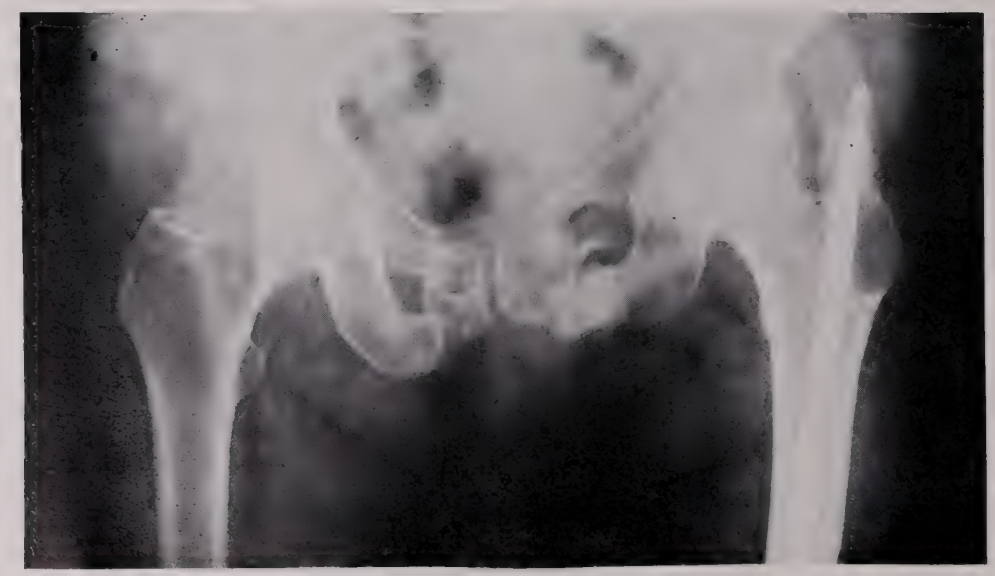

Fig. 8—Healed pelvic fractures nine months after injury.

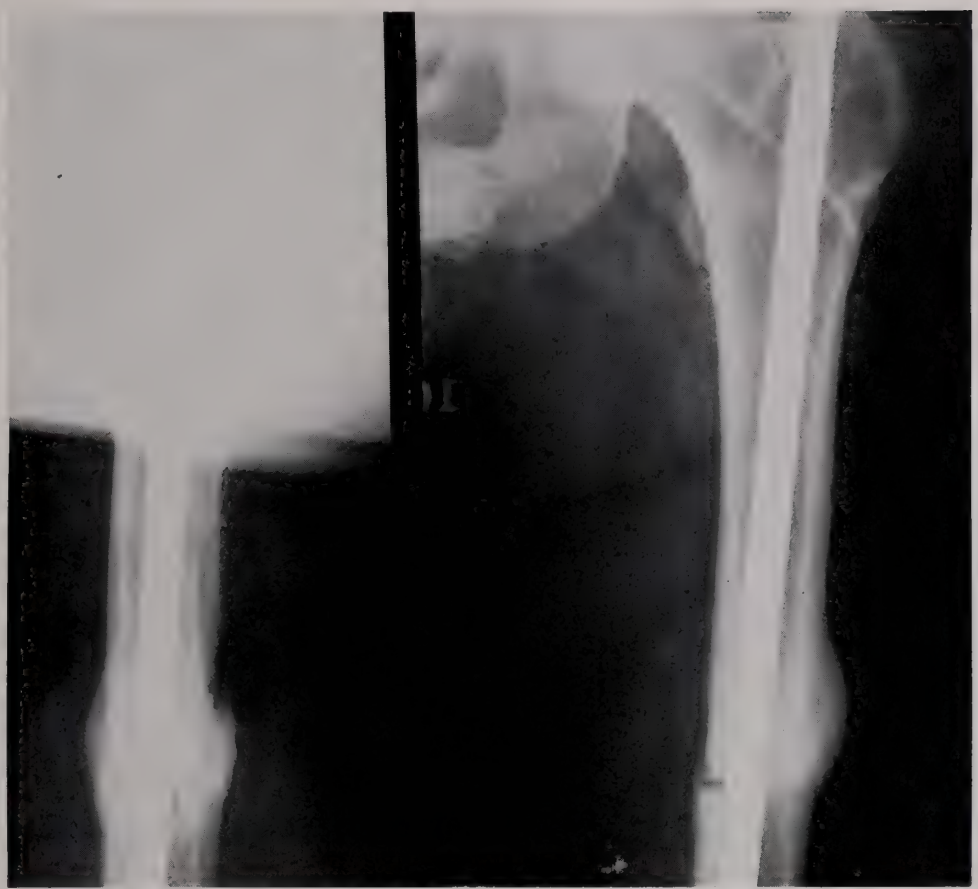

Fig. 9—The left femur nine months after injury.

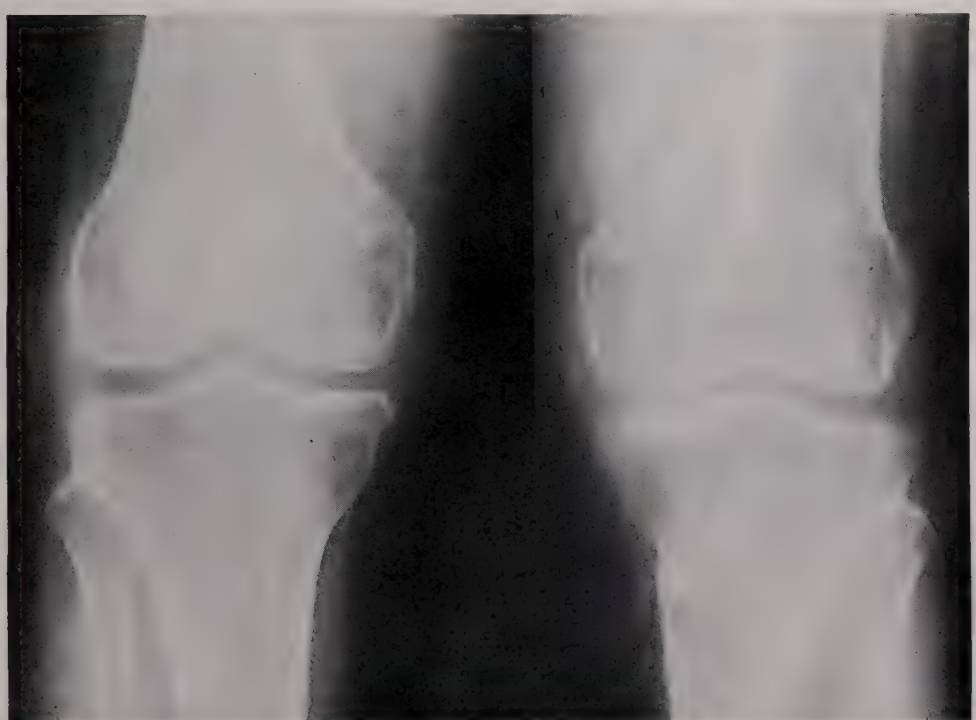

Fig. 10—At nine months after injury the fractures of the right medial femoral condyle and proximal portions of the left tibia and fibula are well healed.

Discussion

This is a presentation of a case in which the patient had multiple major fractures treated successfully by first controlling the shock and then proceeding with rapid definitive treatment of the femoral shaft fracture by internal means and supportive treatment of the other fractures. Close observation of the patient in the intensive care unit during the first week was most important to the success of the treatment. The patient had lost a considerable amount of blood from the compound wound. Also, a pelvic fracture alone in this age group can be a severe injury, and in itself sometimes fatal. Dr. Gustafson, would you comment on the shock treatment?

Dr. Gordon E. Gustafson:*

The initial blood pressure in the emergency room was 156/100 mm Hg. Because of blood loss from the numerous fractures, the blood pressure dropped to 40 mm Hg systolic. Shock was treated initially with two units (1000 ml) of dextran, followed by whole blood. The blood pressure had stabilized at about 120/80 mm Hg at the time the patient arrived in the operating room two hours after her arrival in the emergency room. The third unit of blood had been administered at the conclusion of the operation, about four hours after her arrival in the emergency room. Postoperatively there was a brief period of anuria which responded promptly to the rapid injection of 25 g of mannitol, and to the increased rates of fluid administration and blood replacement to 125 and 200 ml per hour, respectively. Urine excretion started promptly, and subsequently ranged from 30 to 75 ml per hour. Six units of whole blood, 1000 ml of dextran, 1000 ml of lactated Ringer's solution, and 500 ml of 5% dextrose in ¼% normal saline were administered in the first 16 hours. Fluid administration was subsequently decreased to 100 ml of 5% dextrose in ¼% normal saline. The vital signs remained stable thereafter.

The last decade has seen a change in the treatment of hemorrhagic shock. Formerly, emphasis was directed toward the maintenance of an adequate blood pressure. Currently, therapy is directed toward adequate tissue perfusion. Blood pressure and pulse continue to be important parts of the evaluation of any patient with acute hemorrhage. However, the administration of vasopressor drugs is no longer considered good treatment, as these drugs reduce tissue perfusion.

The goal of shock treatment is restoration of adequate tissue perfusion at the cellular level. Blood pressure, pulse, central venous pressure, urinary output, cardiac output, total peripheral resistance, stroke volume, mean transit time, central blood volume, arterial oxygen saturation, and venous oxygen saturation are all helpful indexes of tissue perfusion. Blood pressure, pulse, urinary output, and central venous pressure are most readily measurable, and are helpful in the evaluation of the status and treatment of shock. The measure of urinary output is of great value. If blood pressure is sufficient to maintain an adequate urinary output, tissue perfusion is adequate to maintain the kidneys and probably other organs as well. Central venous pressure is valuable as an index to fluid and blood replacement. If central venous pressure is low, it indicates inadequate replacement. If central venous pressure is elevated, the patient should be watched for right-sided heart failure.

*General Surgery Department, St. Vincent Charity Hospital, Cleveland, Ohio.

A large-bore catheter should be inserted into the central venous system in every seriously injured patient at the time of initial venipuncture. At the same time, a sample of blood should be withdrawn for typing and cross-matching. The catheter can be used for the rapid infusion of fluid and whole blood as well as for the measurement of central venous pressure. A catheter should also be inserted into the bladder. If urinary output does not start promptly, mannitol should be given in addition to adequate fluid and blood replacement.

The appropriate anesthetic in these patients is cyclopropane, because it permits the body to maintain its reflex compensations for a maximal period. It also is a very rapidly reversible agent.

Dr. Alfred:

Due credit in this case must be given to the resident staff in their diligence and astute observation in the postoperative course and management.

Dr. James I. Kendrick:*

Do you think prior knowledge of the left tibia and fibula fractures would have altered your treatment?

Dr. Alfred:

I don't think so. Treating the femoral fracture by traction would require skeletal traction preferably through the tibial tubercle. The fracture of the tibia obviated this. Actually, stabilizing the femoral fracture rendered the treatment of the tibial fracture that much easier. I think the only thing that may have prevented the intramedullary approach would have been a much greater procedure about the hip, such as extensive surgery to remove a nail and plate. As it was, the Smith-Petersen nail was plucked out through a small stab wound, with minimal trauma.

Charles M. Evarts, M.D.†
Cleveland, Ohio

Have Faith

Personally, I should always prefer the patient who believes something, as contrasted to the patient who believes nothing. Give me the patient who believes that a chunk of asafetida worn on a string around the neck will ward off disease, in preference to the patient who sits in complete resignation.

We may sneer at the ridiculous practices of the past, when surgery was a sideline for the town barber and when therapy consisted of little more than bloodletting. And yet many a service man who saw duty in North Africa during World War II, returned with strange stories of the practice of bloodletting among some of the unenlightened Arabs—and even stranger stories of recovery. But are they really any stranger than the stories from our own country, where a distinguished surgeon will have a higher percentage of recoveries at the Mayo Clinic than he will have after returning to his own hospital in Schenectady or Portland? He uses the same skills and the same technique, and possibly he has identical equipment at his command. But the reputation of the Eighteenth Street Hospital doesn't inspire so much faith as does the magic name of the Mayo Clinic in Rochester. And that makes a difference that can be measured in percentages, in the vital statistics column.*

the antacid puzzle

In peptic ulcer:

solved by Mylanta®

aluminum and magnesium hydroxides *plus* simethicone

"will it ease the pain?"

Mylanta helps relieve ulcer pain with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

will it help "my gassy stomach"?

Mylanta *also* contains simethicone: for concomitant relief of G.I. gas distress.

"will this one taste O. K.?"

The *prolonged* acceptance of Mylanta was recently confirmed in 87.5% of 104 patients—after a total of 20,459 documented days of therapy.* *Danhof, I. E.: Report on file.

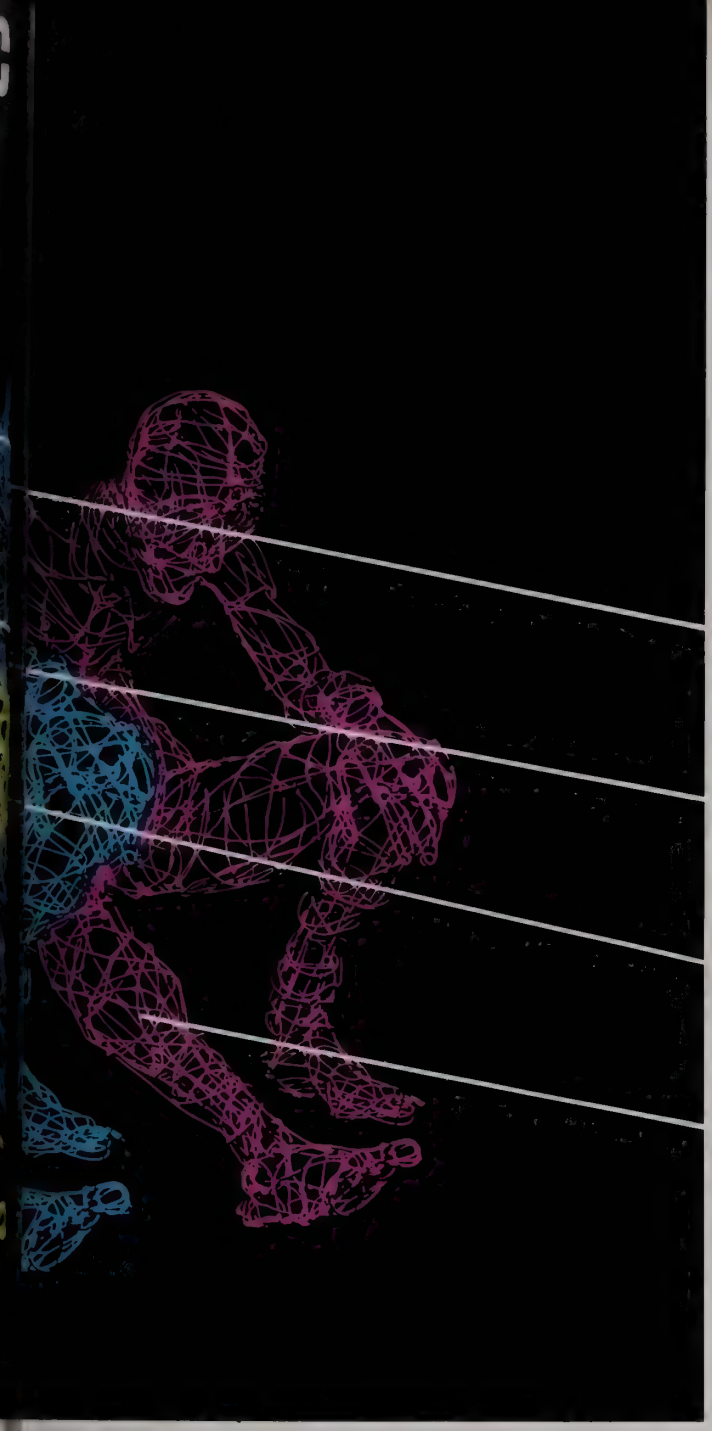
Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. *Dosage:* One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

Stuart Division/Pasadena, Calif.
ATLAS CHEMICAL INDUSTRIES, INC.

a comprehensive hematinic

Description: Each Pulvule® contains—

Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	150	mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin (The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)	7.5	mcg.
Iron, Elemental (as Ferrous Fumarate)	110	mg.
Ascorbic Acid (Vitamin C)	75	mg.
Folic Acid	1	mg.



Indications: Trinsicon® (hematinic concentrate with intrinsic factor, Lilly) is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia.

Contraindications: Hemochromatosis and hemosiderosis.

Precautions: Anemia is a manifestation that requires appropriat investigation to determine its cause or causes.

In pernicious anemia, the use of folic acid without adequat vitamin B_{12} therapy may result in hematologic remission but neu rological progression. Adequate doses of vitamin B_{12} (parentera or oral with potent intrinsic factor as in Trinsicon® [hematini concentrate with intrinsic factor, Lilly]) usually prevent, halt, c improve the neurological changes.

As with all preparations containing intrinsic factor, resistanc may develop in some cases of pernicious anemia to the potentia tion of absorption of physiological doses of vitamin B_{12}. If resis ance occurs, parenteral therapy, or oral therapy with so-calle massive doses of vitamin B_{12}, may be necessary. No single reg men fits all cases, and the status of the patient observed i follow-up is the final criterion for adequacy of therapy. Periodi

You can treat combined deficiencies with

Trinsicon®

—the multifactor hematinic

Vitamin B_{12} plus intrinsic factor (15 mcg. B_{12} activity)—helps provide adequate levels of this important vitamin.

Folic acid (1 mg.)—treats nutritional macrocytic anemias and/or malabsorption syndromes.

Ascorbic acid (75 mg.)—augments the conversion of folic acid to its active form and helps iron absorption.

Iron (110 mg.)—treats hypochromic anemia.

clinical and laboratory studies are considered essential and are recommended.

Adverse Reactions: In rare instances, iron in therapeutic doses produces gastro-intestinal reactions, such as diarrhea or constipation. Reducing the dose and administering it with meals will minimize these effects.

In extremely rare instances, skin rash suggesting allergy has followed oral administration of liver-stomach material. Instances of apparent allergic sensitization have also been reported after oral administration of folic acid.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a standard response in the average uncomplicated case of pernicious anemia.)

How Supplied: Pulvules Trinsicon® (hematinic concentrate with intrinsic factor, Lilly), in bottles of 60 and 500. [032568]

Clinical Path Conference

Weakness and Chronic Heart Failure

Case History

History

A 50-year-old white woman who worked as a bookkeeper was first examined at the Cleveland Clinic on August 17, 1966. She was referred by her family physician because of his difficulty in controlling her congestive heart failure, and his concern about her electrocardiogram that had been interpreted as showing dextrocardia with left ventricular and left atrial enlargement. Her medications included digitoxin, 0.1 mg daily, and a diuretic several times weekly, with potassium supplements.

When she was first seen, the chief complaint was related to extreme weakness of the arms; this was so severe that she could hardly elevate them to comb her hair. She was also experiencing shortness of breath with exertion and had noted intermittent swelling of the feet and ankles. She had been unable to work for four months—since May of 1966.

This illness began in November of 1965, when she first noticed fatigue, weakness, and shortness of breath. These symptoms progressed slowly during the ensuing six months. In addition, anorexia developed and she lost 20 pounds. In May, 1966, the patient was admitted to a hospital in her community, where she remained for two weeks. She was told that there was too much fluid in her lungs because of rheumatic heart disease. She was treated for congestive heart failure, with a resultant additional loss of 10 pounds, disappearance of ankle swelling, and some improvement in breathing. However, the weakness persisted and she was unable to return to work.

Physical Examination

When first seen at the Cleveland Clinic, her weight was 130 pounds, her height, 68 inches. The blood pressure (sitting) was 90/60 mm Hg; the pulse was 78 beats per minute and regular; the oral temperature was 98F. She appeared pale, wan, and chronically ill. The pertinent physical findings were as follows: the neck veins were slightly distended; the lungs were clear; the heart was enlarged, with the point of maximal impulse located in the fifth left intercostal space at the left anterior axillary line; the heart sounds were of fair quality with an increase in the intensity of S_1 at the apex; there was normal splitting of S_2 at the base, and S_2 at the pulmonic area was slightly increased; there was an early diastolic sound audible at the apex; no murmurs were heard; there was no palpable enlargement of the liver or spleen; the extremities were not edematous; the peripheral pulses were full.

Laboratory Proceedings

A roentgenogram of the chest showed 25 percent generalized cardiac enlargement according to the Ungerleider scale. The enlargement was thought to be primarily right ventricular with slight left atrial enlargement. There was an increase in peribronchial markings in both lungs. Fluoroscopy confirmed these impressions. No intracardiac calcifications were noted.

On August 19, 1966, the electrocardiogram showed considerable right axis deviation with relatively large R waves in the right precordial leads. The T waves were diphasic in leads II, III, and AVF, and were inverted in leads V5 and V6.

Results of initial laboratory studies included the following: hemoglobin, 11.9 g/100 ml; cell volume percentage, 37; a leukocyte count of 9,200 per cubic millimeter, and a normal differential count; normal platelets. Urinalysis—pH, 6.5; specific gravity, 1.008; protein, 2 plus; sugar, 0; erythrocytes, many; leukocytes, 10 to 15; casts, 0. Fasting blood sugar, 68 mg per 100 ml; serologic tests negative; sedimentation rate (corrected), less than 0.05 mm/min.

In order to continue diagnostic studies, including cardiac catheterization, she was admitted to the Cleveland Clinic Hospital on September 16, 1966. In the hospital the following additional laboratory data were obtained: serum sodium, 141 meq per liter; serum potassium, 4.5 meq per liter; serum chloride, 102 meq per liter; carbon dioxide, 25 meq per liter; blood urea, 30 mg per 100 ml; urinalysis—3 plus protein; specific gravity, 1.010; 8 to 10 erythrocytes per high-power field; 15 to 20 leukocytes per high-power field; urine culture, sterile; 12-hr Addis count (wet) showed: volume, 760 ml; specific gravity, 1.009; pH, 6.0; protein, 1.44 g per liter or 2.188 g per 24 hr; more than 50 million erythrocytes and leukocytes per 24 hr. The lupus erythematosus cell test was negative. Serum protein electrophoresis—total, 5 g per 100 ml, with 3.7 g albumin; α_1-globulin, 0.3 g; α_2-globulin, 0.3; β-globulin, 0.5 g; γ-globulin, 0.3 g per 100 ml.

Phonocardiography revealed that the early diastolic sound occurred 0.16 second after the second heart sound. An excretory urogram showed normal renal function; the kidneys were not enlarged, and there was a small stone in the inferior calyx of the right kidney.

On September 22, 1966, left- and right-sided heart catheterization studies were done, and cinecoronary angiograms were obtained.

On September 27, 1966, thoracotomy was performed. Oliguria developed postoperatively, with increases in blood urea to 129 mg per 100 ml, blood creatinine to 4.4 mg per 100 ml, and potassium to 6.8 meq per liter. On the fourth postoperative day, while she was being prepared for hemodialysis, cardiac arrest occurred, and despite all attempts at resuscitation, the patient died.

Evaluation

Paul Nickerson, M.D.*:

In discussing the cause of this patient's disease, I believe that several basic questions must be considered before some of the details can be mentioned. First of all, did this syndrome appear at first glance to fit into any one particular grouping of heart disease? Did it seem to be coronary artery disease, myocardial disease, a valvular or structural defect? What role did the lungs or kidneys play in this process, as well as isolated factors such as hypertension or neoplastic obstruction? The history seemed to be rather nonspecific, and, except for an enlarged heart, a diastolic sound, and some variation in the normal intensity of heart sounds on auscultation, few other pertinent findings were elicited. Perhaps more important were the negative findings, which included no chest pain, fever, irregular heart rhythm, high blood pressure, hemoptysis, syncope, cyanosis, heart murmur, orthopnea,† nocturnal dyspnea, or familial heart disease.

Upon initially reading the protocol, the possibility of *primary or secondary myocardial disease* is certainly brought to mind. The evidence of persistent cardiac failure, despite digitalization and repeated diuresis, and the absence of a heart murmur would suggest that primary or secondary myocardopathy was present in this patient. The insidious onset of weakness and fatigue, dyspnea on exertion, and the presence of what can be assumed to be a ventricular diastolic gallop are consistent with this disease, even though these find-

*Fellow in Medicine, The Cleveland Clinic Foundation, Cleveland.
†See Test Your Word Score Page 1083.

ings are nonspecific. Many patients (approximately two thirds) with myocardopathy have systolic murmurs, mainly mitral in origin. They also have other signs and symptoms such as arrhythmia, syncope, and pleuritic or anginal pain. Since the patient we are discussing had none of these signs or symptoms, it seems unlikely that she had primary myocarditis.

Chronic pericarditis is usually of gradual onset and can have presenting symptoms similar to those in this case. Certainly absence of chest pain, and presence of a diastolic sound or knock, without a murmur, could be associated with chronic pericarditis. An electrocardiographic pattern resembling the changes seen in right ventricular hypertrophy, a low blood pressure, decreased pericardial pulsations as shown by fluoroscopy, and an enlarged heart shadow on the roentgenogram are other signs consistent with chronic or constrictive pericarditis. However, the absence of a low-voltage QRS and pericardial calcifications, militate against a diagnosis of chronic pericarditis in this patient.

Another diagnosis that should not be overlooked is that of *arteriosclerotic heart disease*. Arteriosclerotic heart disease can become evident by cardiac enlargement with congestive failure without prior warning from angina or myocardial infarction, even though this mode of onset is unusual. However, this patient lacked even the indirect evidence of such a possibility. She had a normal fasting blood sugar value, no hypertension, no metabolic disease, and there is no mention of a positive family history of arteriosclerosis. A blood cholesterol value was not determined, and the presence of arcus senilis was not mentioned. It might be expected that the presence of extreme right axis deviation and evidence of predominant right ventricular hypertrophy, as noted in this patient, would be extremely rare. At this time it would be well to examine the roentgenograms.

Radiology

William R. Pudvan, M.D.*:

Two sets of roentgenograms of the chest of this patient are available; the first set was taken in August of 1966, and the second approximately five weeks later. The chest findings are interesting, inasmuch as there are moderate cardiomegaly and a straightening of the left cardiac border, suggesting prominence of the pulmonary artery segment in this region. The configuration of the heart would suggest right ventricular enlargement, particularly on the left anterior oblique view, since an increased transverse cardiac diameter is seen. I am not convinced that there is much evidence of left ventricular enlargement present on these films. In addition, on the right anterior oblique view, the barium-filled esophagus is not abnormally displaced or deviated; so, although there is evidence of enlargement of the right side of the heart and a prominent pulmonary artery segment, I see no evidence of left atrial enlargement. In the lung fields, there are prominent pulmonary vascular markings extending all the way to the lateral chest walls and, in addition, some septal lines that can be seen, particularly in the right costophrenic angle.

These findings would indicate pulmonary venous hypertension. This, plus enlargement of the right side of the heart, would certainly suggest mitral involvement. In the absence of definitive evidence of an enlarged left atrium, it is interesting to speculate that something might be interfering with the patient's pulmonary venous return. If I am correct in assuming that the left

*Division of Radiology, The Cleveland Clinic Foundation, Cleveland.

atrium is not enlarged, I would suggest on the basis of these roentgenograms that the interference is proximal to the mitral valve, either within the left atrium and not causing enlargement, or, proximal to that, some type of lesion affecting the pulmonary venous system. The second set of roentgenograms merely shows an accentuation of these findings, with moderate increase in heart size and increased prominence of the septal lines suggesting pulmonary venous hypertension. From the radiologic viewpoint alone, I would favor a diagnosis of myxoma of the left atrium; my second choice would be mitral stenosis.

Doctor Nickerson:

Would you show the electrocardiogram, please?

This tracing shows extreme right axis deviation; I estimate it to be about 130 degrees. Certainly this is normal sinus rhythm and there is a normal PR interval. In the precordial leads, there is extreme clockwise rotation with the transition zone out in V5 with diphasic waves in leads 2, 3, and AVF, and inversion of the T waves in leads V5 and V6. There is sagging of the ST segments in leads 2 and 3, suggestive, perhaps, of digitalis effect. Also, the diaphasic T waves in leads V1 and V2 suggest right atrial enlargement, and only the R wave present in V3R and the predominant R wave in V1, in the presence of small QRS complexes, suggests right ventricular hypertrophy.

Because of the striking findings on the electrocardiogram, indicating right axis deviation, and a roentgenogram that is compatible with right ventricular hypertrophy and an enlarged pulmonary artery segment, some mention of *pulmonary arterial hypertension* might lead us further toward the diagnosis. However, upon further consideration, primary pulmonary hypertension, thrombosis of major pulmonary vessels, and multiple pulmonary emboli as causes of this illness can be excluded.

Congenital heart disease in some cases can show changes similar to those seen in the roentgenograms and the electrocardiogram, but I shall completely disregard this diagnosis because no murmur is present. Cor pulmonale might be considered, but not that associated with chronic obstructive lung disease, since there is no evidence for this.

Lastly, *valvular heart disease* should be mentioned here. We think of valvular disease as being accompanied by murmurs, but despite the absence of a murmur in this case we should think of mitral stenosis, as Doctor Pudvan suggested when he examined the roentgenograms, even though there is no evidence of left atrial enlargement. The patient did have pulmonary venous hypertension, right ventricular enlargement, and possibly pulmonary arterial hypertension. I think the question then to be asked is: "How could this patient have such a lesion in the absence of a documented murmur?" This could be an instance of what has been called "silent" mitral stenosis even though I am well aware of the fact that most of the cases in this category are due to incomplete auscultation. Those who believe that there are some cases of true silent mitral stenosis think that this aberration is related to severe pulmonary arterial hypertension with resultant low cardiac output. This patient had a low blood pressure in the range of 90/60 mm Hg. Her symptoms could be consistent with a diagnosis of mitral stenosis, even though she did not have orthopnea and hemoptysis. The possible mechanism of silent mitral stenosis is its association with massive thrombi in the left atrium; however, in this instance, atrial fibrillation is almost always present.

Another cause of left ventricular inflow obstruction should be considered—

primary cardiac tumors. Three fourths of these tumors are benign; and of the benign tumors, the majority are myxomas located in the left atrium. With myxoma of the left atrium, the clinical course is shorter and develops more rapidly than that of mitral stenosis. There is usually evidence of arterial emboli, though the incidence of atrial fibrillation is lower than that seen with stenosis. However, even with myxoma, a murmur should be present. It is possible that at the time of examination, the tumor was not in a position to obstruct the valve, and the murmur was missed. In conclusion, *silent mitral stenosis with severe pulmonary arterial hypertension,* and *myxoma of the left atrium,* should be considered the two best possibilities.

Doctor Nickerson's Diagnosis:

(1) Rheumatic heart disease with mitral stenosis, severe pulmonary hypertension, cardiac enlargement, congestive heart failure.

(2) Myxoma of left atrium.

Leonard L. Lovshin, M.D.*:

Thank you, Doctor Nickerson, for an excellent discussion. This was a patient of William L. Proudfit, M.D. I shall now call upon him to make a few comments and to offer his own clinical diagnosis.

William L. Proudfit, M.D.†:

There are some points that were not completely brought out in the protocol, and therefore Doctor Nickerson didn't have a chance to be benefited by this knowledge—or be confused by it. First of all, the disease progressed rapidly. This woman was referred to us with the diagnosis of mitral stenosis, and, ordinarily, patients with this condition do not decline so fast. This immediately made us suspect that mitral stenosis was not the cause of the illness. In addition, this woman was extremely weak and had lost a good deal of weight; neither of these is characteristic of mitral valvular disease. On examination, there were several unusual findings. The mitral first sound was accentuated; this would not be unusual in mitral stenosis, but she had no mitral diastolic murmur. She also had another unusual finding; the protodiastolic sound could be heard clearly in the back. I can't say that I ordinarily listen for protodiastolic sounds in the back, and this, I must admit, confused me somewhat. Previously I have heard loud sounds in this region, but only in patients who have had myxoma of the left atrium. This sound appeared too late in the cycle for myxoma of the left atrium, since it occurred 0.16 second after the second heart sound. Perhaps more emphasis should have been placed on the urinary changes. She did have an abnormal urine; there were an increased number of erythrocytes and 2+ protein even when she was not in congestive failure. As the workup progressed, we narrowed the possibilities to constrictive pericarditis, primary or secondary myocardial disease, or myxoma of the left atrium. I believed that both myxoma and constrictive pericarditis could be excluded because the sound occurred so late and that therefore we were hearing a protodiastolic gallop rhythm. This left us with a diagnosis of *myocardial disease.*

Doctor Proudfit's Diagnosis:

Primary or secondary myocardopathy.

Doctor Lovshin:

We shall now hear from Lawrence J. McCormack, M.D., who will give us the diagnosis based on myocardial biopsy and autopsy findings.

*Department of Internal Medicine, The Cleveland Clinic Foundation, Cleveland.
†Department of Clinical Cardiology, The Cleveland Clinic Foundation, Cleveland.

Lawrence J. McCormack, M.D.*:

Microscopic study of myocardium from the left ventricle and left atrium obtained at the time of surgery showed severe amyloidosis. At the time of autopsy the heart weighed 500 g; there was dilatation of the left atrium and right ventricle, accompanied by moderate hypertrophy. There was only slight hypertrophy of the left ventricle, but no dilatation. The coronary arteries were normal; there was no evidence of pericarditis.

Microscopic examination disclosed heavy deposition of amyloid in the myocardium and surrounding the blood vessels. Study of special sections showed deposits in the sinus node and atrioventricular bundles.

The problem of pulmonary hypertension can be explained by the fact that the lungs were severely and diffusely involved. Amyloid was also demonstrated, in lesser amounts, in the spleen, liver, pancreas, kidneys, and bowel.

The cause of the severe oliguria that occurred after the operation is not entirely clear, since the kidneys were not greatly affected by amyloid. Incidentally, there was a small renal stone that was of no clinical significance.

Anatomic Diagnosis:

Disseminated primary amyloidosis, and cardiomegaly (500 g) due chiefly to hypertrophy and dilatation of the right ventricle and left atrium.

Discussion

Doctor Lovshin:

I should like to state that Doctor Proudfit suggested the possibility of amyloidosis at the time of his initial examination, and he noted this in the record. Since he did not mention this in today's discussion, I assume that he either is overly modest or is somewhat forgetful.

This patient was studied in the cardiac laboratory by William C. Sheldon, M.D., of the Department of Cardiovascular Disease and Cardiac Laboratory, and some valuable information was obtained. The conclusion of his report read as follows:

> "Restrictive cardiopathy with impaired ventricular filling and secondary left atrial and pulmonary hypertension of moderately severe degree. Suspect this is primary myocardial disease. Primary amyloidosis? Cannot exclude constrictive pericarditis."

I should like to know what findings at the time of catheterization of the heart suggest possible primary myocardial disease.

Doctor Sheldon:

I shall try to point out some of those features. When we saw the patient the biopsy had not yet been done and the diagnosis was in doubt. We were faced with the problem of a patient with signs of pulmonary hypertension and a history of symptoms consistent with cardiac failure. We performed complete right- and left-sided heart catheterization studies, and the first thing we discovered was elevation of all of the intracardiac pressures. The patient did, indeed, have moderate pulmonary hypertension, but she also had elevation of the end-diastolic pressure in the left ventricle and significant elevation of the left atrial pressures. In recording a continuous tracing from the left atrium to the left ventricle there was no gradient during diastole.

One of the interesting findings during catheterization was the contour of

*Division of Pathology, The Cleveland Clinic Foundation, Cleveland.

the pressure tracing in the right ventricle, which showed an early diastolic dip with a late diastolic plateau. This is commonly seen in various types of extrinsic restriction of diastolic filling and can be due either to pericardial or to myocardial disease, or, in some cases, to extreme myocardial hypertrophy. Therefore we tried to solve the problem with some motion pictures (could you show the film please?).

One of the considerations, in view of the right axis deviation on the electrocardiogram, was the possibility of primary pulmonary hypertension or multiple pulmonary emboli. The first injection of contrast medium was into the main pulmonary artery, and this shows the main pulmonary artery in the frontal projection. You will notice that there is the normal rapid-velocity flow through the pulmonary circulation, and the total venous drainage from the lungs is directed to the left atrium, which is seen here in the frontal projection. The left atrium is perhaps slightly enlarged. When one looks carefully at the primary, secondary, and even some of the tertiary pulmonary arterial branches, they appear perfectly normal in caliber. We cannot identify a localized or diffuse obstructive process that might indicate multiple pulmonary emboli, nor can we see the secondary changes that occur in patients with primary pulmonary hypertension. This particular injection also served to exclude the presence of anomalous drainage of the pulmonary veins. It also excludes a left-to-right shunt at the atrial level, since demonstration of the left atrium is quite good.

This selective opacification of the left atrium shows it to be definitely enlarged. The catheter has been placed retrograde across the mitral valve and we can see no filling defect, mass, or tumor within the left atrium. You will remember that the patient had sinus rhythm; despite this, there is extremely poor amplitude of the atrial contractions.

This view shows the left ventricle in the right anterior oblique projection; it is not the dilated chamber we might have expected to see. The diastolic size is quite normal. In motion study during diastole there seemed to be a rather thick zone of myocardium between the cavity and the external surface. This frame shows the chamber at the peak of systole, and the end-systolic volume is minimally increased. The striking thing is that, during diastole, the chamber reaches a maximal end-diastolic size and then fails to expand further as the atrium expels its contents. The ventriculogram suggests restricted diastolic filling of the left ventricle.

Because we also had to be completely sure that the patient did not have some unusual form of coronary artery disease, we opacified the coronary arteries and saw that both the right and the left vessels were normal. There was a dominant right coronary artery pattern with no evident atherosclerotic changes.

On the basis of these studies we showed that there was restricted diastolic filling both of the left and of the right ventricles, secondary hypertension and enlargement of the left atrium, secondary pulmonary hypertension, and right ventricular hypertension. The pictures did not suggest the usual hypertrophic process so often seen in idiopathic hypertrophic subaortic stenosis. Therefore the restricted diastolic filling could be due to a myocardial infiltrative process, or it could also be due to an extramyocardial condition such as thickened pericardium. We did attempt to demonstrate the width of the right atrial wall; it appeared to be somewhat thicker than usual, and we could not exclude the possibility of pericardial thickening.

Some of our findings were identical with those seen in other patients with primary amyloid disease affecting the heart. One is the relatively small size of the ventricular chambers, as compared to other forms of primary cardiomyopathies of the nonhypertrophic type. These usually show severe dilatation of the ventricles. Another feature is that during diastole the maximal ventricular size is achieved very early. As diastolic filling continues, and during atrial injection in the presystolic phase of the heart cycle, there is little further expansion of the left ventricle. These findings all indicate a restrictive process, but they do not tell us whether this restriction is in or around the myocardium.

Doctor Lovshin:

Apparently this was the definitive study that led to the decision in favor of thoracotomy for pericardial exploration and myocardial biopsy. I shall now call on our distinguished Visiting Professor of Medicine, W. Proctor Harvey, M.D.

W. Proctor Harvey, M.D.*:

This is a very interesting case. In looking back on the electrocardiograms I don't remember the low voltage that has previously been reported to be common in patients with cardiac amyloidosis. This may be a valuable clinical clue in differentiating the condition of a patient of this type from some other form of cardiomyopathy, especially since many of the other findings can be identical. It would be very unusual for patients with myocardial disease not to have an atrial sound; this finding has been extremely common in our own group of patients. I think this has been a most instructive case and the presentation excellent.

Doctor Lovshin:

Are there any questions?

Nelson G. Richards, M.D.†:

There's just one question I should like to raise here. The patient's chief complaint was that of a myopathy. Among persons who have cardiac disease how often do you find that they complain of inability to comb their hair or lift their arms above their heads unless it be a diffuse disease involving the rest of the body as well as the heart?

Doctor Proudfit:

Difficulty in lifting the arms is not unusual in heart disease, because periarthritis of the shoulders is so common in coronary disease. Since a neurologist is asking the question, I assume he is referring to something else. General weakness is characteristic in patients who have congestive heart failure, and sometimes you do see patients with this condition who have difficulty combing their hair. I do admit, however, that this woman's weakness was out of proportion to other manifestations of the heart disease.

Doctor Lovshin:

Doctor Richards, I think Doctor Proudfit is admitting in a roundabout way that the patient's severe weakness in the arms was due to myopathy, and that the cardiologists could have paid more attention to it. I have no doubt that if this patient had been seen originally in the Department of

*Professor of Medicine, Director, Division of Cardiology, Georgetown University School of Medicine, Washington, D.C.

†Department of Neurology, The Cleveland Clinic Foundation, Cleveland.

Neurology, you would have arrived at the same diagnosis—and perhaps more easily!

Anita M. Klein, M.D.*:

Was there any evidence of myopathy in skeletal muscle at the time of autopsy?

Doctor McCormack:

Unfortunately we did not examine a specimen of skeletal muscle. Apparently, everyone was too interested in the myocardium. However, this is a pertinent question, because in amyloid disease, functional deficit does not necessarily correlate with the amount of abnormal material seen microscopically. In the kidney, for example, you may find only minute amounts of amyloid in the renal glomeruli, and yet significant proteinuria may occur. In muscle you may find only a small amount of amyloid ringing the blood vessels even though there had been profound weakness. The explanation for this is not yet available. When you suspect amyloid disease and you send in a biopsy specimen, please warn us, because many times the amyloid can be demonstrated only with special stains, and we will not see anything in the routine hematoxylineosin preparations. If the biopsy specimen is a piece of myocardium, we need no advance warning, because all such material is routinely screened for amyloid.

Doctor Harvey:

I should like quickly to make a point. The incidence of amyloid disease is increasing as people live longer. In recent years, more and more cases are being documented in the medical literature, many of them from the older age groups.

Doctor Nickerson:

I should like to ask Doctor Proudfit how he explains the very loud diastolic gallop?

Doctor Proudfit:

Loud ventricular gallops are common in patients who have amyloid or other primary myocardial disease. In contrast to other types of heart disease, these gallops are apt to remain loud when the rate is slowed as a result of adequate treatment for congestive heart failure. Thus, even when congestive failure disappears and the clinical manifestations improve, this auscultatory sign characteristically remains strong. I still don't know why the gallop was heard over the back.

Leonard L. Lovshin, M.D.†
Cleveland, Ohio

Renal Arterial Disease and Hypertension

An Analysis of Selective Renal Arteriography
in 1500 Consecutive Patients

INCREASING EXPERIENCE with renal arteriography has shown that a variety of changes may be observed in patients with renal arterial disease, and accumulation of data from pathologic studies of diseased renal arteries has indicated that several disease processes may affect the renal arteries.

The arteriographic appearance of the most common renal artery lesion, atherosclerosis, is well recognized. Differing arteriographic finding have appeared in the non-atherosclerotic diseases. Despite dissimilarity in the histologic characteristics, these non-atherosclerotic lesions have been indiscriminately grouped under the term fibromuscular hyperplasia.

In a retrospective correlative analysis of autopsy and surgical specimens of renal arteries with renal arteriograms, McCormack and Associates[1] have shown that the various renal arterial diseases usually have characteristic arteriographic features, so that, when a sufficient length of renal artery is affected, the pathology of the disease process may be predicted from the arteriogram. However, the relative frequency of the various renal arterial diseases in this retrospective study was influenced by the fact that most of the material was obtained from patients who were considered candidates for surgical treatment of renal arterial disease which might be responsible for their hypertension. In addition, accumulation of sufficient pathologic material for study required that many of the arteriograms used in the correlative analysis were derived from the period when translumbar aortography was the primary arteriographic method for study. Dilution of contrast material by aortic blood and overlap of renal arteries by filling of extrarenal arteries, the two major disadvantages of aortographic techniques, often precluded complete and accurate delineation of the entire renal arterial system of both kidneys.

The present study is an analysis of renal arterial disease in 1500 consecutive hypertensive patients studied by selective renal arteriography. Its purpose is to define the incidence, type and distribution of the various categories of renal arterial disease in a large group of selected hypertensive patients. Included are the findings in 100 patients, previously reported.[2]

Materials and Methods

One thousand five hundred hypertensive patients who were studied consecutively were selected, usually on the basis of the following clinical criteria: Onset of hypertension below age 40; documented recent onset of hypertension in all groups; exacerbation or acceleration of existing hypertension or an abdominal bruit in association with hypertension. Some were selected because of disparity in renal sizes, nonfunctioning of a kidney or difference in renal function demonstrated by intravenous urography.

Renal arteriography was performed in the majority of the patients by the Seldinger technique[3] of percutaneous femoral catheterization. In some patients with aorto-iliac occlusions, the catheter was introduced by open brachial arteriotomy. A pre-moulded Odman-Ledin catheter* of medium size (green) was used in most studies. Using image intensification fluoros-

*A.B. Kifa Co., Stockholm.

copy, selective renal arteriography was carried out using 4 to 8 cc of contrast material (Hypaque 50%). In all patients, aortography was performed by pressure injection of 20 to 40 cc of contrast material (Hypaque 75%).

Radiographs following selective injections were obtained in anteroposterior and posterior oblique projections and aortographic films in the anteroposterior projection. As individual circumstances warranted, aortograms were also obtained in the erect or oblique projections.

Arterial diseases were categorized using the criteria of McCormack et al.[1] Lesions were classified according to their primary location in the vessel wall. There are two that primarily affect the intima: atherosclerosis and intimal fibroplasia. Three types predominantly involve the media: medial fibroplasia with aneurysm, fibromuscular hyperplasia and subadventitial fibroplasia. Using the arteriographic criteria which have been set forth in this classification, we have been unable to differentiate consistently fibromuscular hyperplasia from intimal fibrosis. Accordingly, in the present study, these two types of diseases have been grouped.

A category of fibrous disease of undetermined type has been included because either the features were not sufficiently characteristic or the length of the artery affected was too short for the manifestations of the particular type of arterial disease to be discerned.

Results

Of the 1500 patients studied, renal arterial disease of varying severity and type was demonstrated in 649 (43.3 percent) patients and classified into groups on the basis of the arteriographic characteristics: atherosclerosis, fibrous disease, a combination of atherosclerosis and fibrous disease, renal artery aneurysms, renal artery aneurysms associated with atherosclerosis, and a miscellaneous category including embolic and thrombolic disease and complete occlusion of the renal artery (Table 1).

Atherosclerotic Renal Artery Disease

Atherosclerotic disease of the renal arteries was observed in 62 percent of the patients with arterial disease (Figure 1). Of these patients, 65.2 percent were males. The majority of the patients, 87.5 percent, were in the fifth, sixth or seventh decades of life (Table 2). Stenosis was estimated to be less than 50 percent in 64.6 percent of the patients, while 35.4 percent had lesions of greater severity. Bilateral disease was present in 34.9 percent of the patients, and in those patients with unilateral disease, there was no difference in the frequency of right and left-sided involvement. Lesions of the orifice and proximal centimeter of the renal artery were found in 58 percent of the patients, of distal main renal artery disease in 24 percent, and of interlobar branches alone or in association with main renal artery disease, in 18 percent. One fourth of the patients with lesions less than 50 percent occlusive had disparity in renal lengths of 1.0 cm or more as measured on the intravenous urogram. The incidence of disparity in lengths was 56

percent in those patients with lesions of greater severity.

Non-Atherosclerotic Renal Artery Disease

One hundred ninety-three patients had non-atherosclerotic disease as judged by the arteriographic appearance. Of these, 88.6 percent had fibrous disease alone and the remaining, fibrous disease in combination with atherosclerosis.

One hundred forty-nine patients (77.2 percent) had lesions classified as medial fibroplasia; 16 (8.3 percent), subadventitial fibroplasia; and 17 (8.8 percent), either fibromuscular hyperplasia or intimal fibrosis (Table 3 and Figures 2, 3 and 4). In 10 patients (5.2 percent) the disease did not appear to be atherosclerotic but was not characteristic of any of the fibrous diseases classified above. One patient, age 18 years, who received radiation therapy to the retroperitoneum at 18 months of age, following surgical resection of a Wilms' tumor, was found to have severe fibrotic disease of the aorta and the two renal arteries supplying the remaining kidney when the patient was re-examined because of hypertension at the age of 18 years.

Excluding those patients who had both fibrous and atherosclerotic lesions, 80.4 percent of the patients were females. At the time of arteriography, the majority of these patients were in the fifth decade (48.0 percent) with the fourth and sixth decades being next in frequency (20.1 percent and 15.1 percent respectively). See Table 2.

Two thirds of the patients were judged to have lesions less than 50 percent occlusive. Involvement of the renal artery distal to its first centimeter was found in 95 percent of the patients. Of these, 35 percent affected only the main renal artery, 47 percent the main artery and branches, and branch involvement only in 13 percent.

Almost half of the patients (45.2 percent) had bilateral disease. Unilateral involvement was considerably more frequent on the right, being observed in 80 of the 98 patients (81.6 percent).

Bilateral renal artery involvement was present in 48.8 percent of patients with medial fibroplasia. Of the remaining patients with unilateral involvement, 85.5 percent had right-sided involvement. Bilateral disease was present in 25 percent of the patients with subadventitial fibroplasia, and of those with unilateral disease, three-quarters had right renal artery disease.

There were 17 patients categorized arteriographically as having either fibromuscular hyperplasia or intimal fibrosis. Of these, six had bilateral disease, and eight of the eleven with unilateral disease had right renal artery involvement.

Considering the fibrous diseases collectively,

	404 (100.0)	264 (65.2)	140 (34.8)	179 (100.0)	35 (19.6)	144 (80.4)

one third of the patients with lesions less than 50 percent occlusive, had a difference in renal size as determined by measurement of renal length. One half of patients with lesions more than 50 percent occlusive had disparity in renal size.

Other Lesions

Coexistence of atherosclerosis and medial fibroplasia was found in 14 patients and the frequency of the more stenotic lesions was higher than in those patients with either atherosclerosis or medial fibroplasia alone.

Aneurysms with or without other lesions of atherosclerosis were present in 40 patients, and there was no predilection for involvement of either side. All were located in the distal renal artery and most originated from interlobar branches.

In a miscellaneous category were 12 patients who had emboli or thrombosis of a branch or complete occlusion of the main artery, the latter without features which would allow diagnosis of the type of disease which produced the thrombosis.

The occurrence of single and multiple renal arteries was considered with reference to the presence of renal arterial disease. Thirty-five percent of the patients without renal arterial disease had multiple renal arteries as compared with 32 percent of the hypertensive patients with renal artery disease. This incidence was similar to a control group of 390 normotensive patients in which 32 percent had multiple renal arteries.

The presence of multiple renal arteries was also considered with reference to the various types of lesions which were demonstrated. The findings (Table 4) showed no significant variation in the various categories, with the exception of the miscellaneous category in which there were only 12 patients. Further, there was no trend toward multiple renal arteries in the four types of fibrous disease (Table 5). The higher incidence of single renal arteries in patients with subadventitial fibrosis is not significant because of the small group and the higher incidence of solitary kidneys.

Discussion

The true incidence of renal arterial disease in hypertensive patients is difficult to determine. While some degree of selection of patient material can be eliminated by examination of necropsy material, this type of examination

does not lend itself well to determination of the extent of renal arterial disease. Varying degrees of patient selection for renal arteriography certainly tend to influence the incidence of disease. As indicated earlier, patients in the present series were chosen because of the presence of "inappropriate" hypertension or because of abnormalities on the intravenous pyelogram. The incidence of renal arterial disease of 43.3 percent in this series is approximately the same (52 percent) as reported earlier in a group of 100 relatively unselected patients.[2] Both of these figures are higher than previously reported from this institution. In 1959 and 1961,[4,5] 28 percent of the patients in whom translumbar aortograms were done were found to have arterial disease. Another feature which distinguishes the present series from earlier reports is the greater frequency of branch arterial disease. Lesions of the primary renal arterial branches were encountered in 15.4 percent of the patients who had atherosclerosis and 57.6 percent of the patients with fibrous disease of the renal artery. The difference is presumably due to improved visualization of arterial branches made possible by the selective technique.

While various disease processes which affect the renal artery may produce stenosis, atherosclerotic disease is the most common (62.1 percent). The first reports[6] of the pathology of non-atherosclerotic disease originating from this institution indicated that most disease that was not atherosclerosis represented a type of process in which muscular hypertrophy was prominent, and the name fibromuscular hyperplasia was used to describe this condition. These reports, however, described the findings in a small number of arteries. As experience has increased, it has become apparent that most of the lesions which are not atherosclerotic do not have muscular hyperplasia as a prominent portion of the histologic characteristics, but rather collagen deposition. Classification of non-atherosclerotic disease used in this report takes into consideration a variety of disease processes based upon the predominant microscopic features and the primary location of the lesion in the vessel wall. It is similar to that described by Hunt and associates[7] but has the additional advantage that a rather close arteriographic-pathologic correlation is possible.

As experience has increased, it has also become apparent that the arteriographic features of fibromuscular hyperplasia and intimal fibrosis closely resemble each other and therefore cannot be distinguished. However, the arteriographic appearance of both of these lesions is distinctly different from that of medial fibroplasia and subadventitial fibrosis.

Summary

On the basis of an arteriographic correlation with histologic material, diseases of the renal artery have been divided into those affecting the intima: atherosclerosis and intimal fibroplasia; and those affecting the media: medial fibroplasia, fibromuscular hyperplasia and subadventitial fibrosis. Renal artery disease was encountered in 649 (43.3 percent) of the patients. Of these, 62.1 percent had lesions of the atherosclerotic type and 25.2 percent lesions of the non-atherosclerotic type. Atherosclerotic lesions were predominantly located in the proximal portions of the renal artery and fibrous lesions in the distal renal artery and primary branches. The peak incidence of detection of atherosclerosis was in the fifth, sixth and seventh decades and 65.2 percent of the patients were males. Fifty percent of the patients with fibrous disease were in the fifth decade and 81.8 percent of all patients with fibrous disease were females. Three fourths of patients with fibrous disease had medial fibroplasia. Stenotic disease of more than 50 percent was present in approximately one third of the patients with atherosclerosis and fibrous disease. The frequency of reduction of renal size in the kidney involved with renal arterial disease increased with the severity of the stenosis. However, in both the patients with atherosclerosis and fibrous disease, a significant percentage of patients with stenotic disease more than 50 percent did not have discrepancy in renal size. The incidence of renal arterial disease was the same in patients with single and multiple renal arteries.

Sources of sinus headache

REGION OF SENSATION

FRONTAL SINUS—headache localized over the frontal region, commonly beginning in the morning. Eyes painful to touch, may be slight swelling over eyes, puffy eyelids.

SPHENOID SINUS—most difficult to diagnose. Headache or sense of pressure over vertex. May be pain in ear or mastoid region.

MAXILLARY SINUS—headache and tenderness under eyes at top of cheekbones, usually starting in early afternoon. Possible swelling of cheek. Pain in jaw and back teeth.

ETHMOID SINUS—headache, tightness in upper part of bridge of nose and well down its sides. Pain, deep-seated behind the eyes and in inner corners of the eyes.

TURBINATES—pain along medial and lateral walls of the inside of the nose. Headache in frontal region, along supraorbital ridge, a feeling of fullness in the head.

Source of symptomatic relief

SINUTAB

Sinus headache is often a reflection of congestion in the nasal mucosa. The pain that results in the various regions of the head may help in determining the particular structure(s) responsible. The Sinutab formula is specifically designed for symptomatic relief of sinus headache and nasal congestion. **Sinutab** *not only* **provides an effective decongestant** — to reduce mucosal engorgement and facilitate freer breathing — *and* **an antihistamine** — to help reduce edema and excessive secretions — but it *also* provides, in contrast to other leading decongestants, **two analgesics** for immediate relief of pain and discomfort.

And, too, the Sinutab dosage schedule of 2 tablets, *q.* 4 *h.* permits controlled and continuing analgesic relief.

Adverse Reactions: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive or operate machinery if drowsiness occurs. Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

Each tablet contains 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

SPECIFIC FORMULA SINUTAB® FOR SINUS HEADACHE

Also Available on Prescription:

Sinutab® with Codeine.* Each tablet contains 15 mg. (¼ gr.) codeine phosphate (Warning: May be habit forming), 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

Sinutab® Pediatric Suspension. Each 5 ml. teaspoonful contains 300 mg. acetaminophen, 12.5 mg. phenylpropanolamine HCl, and 10 mg. phenyltoloxamine citrate.

*Subject to Federal Narcotics Regulations.

For 1 complimentary bottle of 30 Sinutab tablets, write: J. S. Travis, Warner-Chilcott Laboratories, Morris Plains, N.J. 07950. Please mention this journal.

Grand Rounds

Gastrointestinal Causes of Megaloblastic Anemia

SINCE CASTLE and Townsend's[1] experiments showed that the underlying defect in pernicious anemia was a failure of gastric secretion of intrinsic factor, the relationship between gastrointestinal disorders and megaloblastic anemia has been widely studied. Many questions still remain unanswered, but a comprehensive view of this relationship has been established, and it is the object of this paper to review the subject from a clinical standpoint (Table 1).

Lack of vitamin B_{12} (Castle's original "extrinsic factor"), or of folic acid, leads to megaloblastic anemias that are morphologically indistinguishable.

However, since these substances are metabolized variously by the gastrointestinal tract, it is sometimes possible to infer from the clinical picture which substance is likely to be absent. Although in this report we are concerned mainly with megaloblastic anemia, it must be kept in mind that a deficiency of vitamin B_{12} or of folic acid affects many systems in addition to the hematopoietic system.

Man and other higher forms of animal life are unable to synthesize vitamin B_{12} and have to rely on bacteria as the primary source. The vitamin is present in almost all foods of animal origin, and the average American diet provides approximately 15 μg per day, of which about 10 percent is actually absorbed, and this quantity is not much greater than the daily adult requirement of 1 μg. However, dietary deficiency of vitamin B_{12} seldom occurs except in strict vegetarians. This ingested vitamin B_{12} combines with the intrinsic factor secreted by the fundus of the stomach, possibly by the parietal cells.[2] The exact nature of the reaction between the intrinsic factor and vitamin B_{12} is not known. However, there is no doubt that lack of the intrinsic factor leads to failure to absorb vitamin B_{12}.

Another unique feature of vitamin B_{12} digestion is that the vitamin is absorbed almost exclusively in the terminal few feet of the ileum.[3,4] The absorption of a molecule as large as vitamin B_{12} almost certainly involves a specific mechanism.[5] Although the exact nature of this mechanism is not clearly understood, pinocytosis at specific absorption sites in the ileum is probably involved.[6] Evidence indicates that vitamin B_{12} is separated from the intrinsic factor before being absorbed; but the suggestion that a "releasing factor" may be involved[7,8] has not been confirmed. When vitamin B_{12} is ingested in large amounts, absorption can take place in the upper jejunum by means of mass action, thus bypassing the intrinsic factor mechanism.[5] The total body stores of vitamin B_{12} amount to from 1 to 2 g.[9] On the basis of a daily absorption of 1 μg,[10] it may be calculated that it can take as long as seven years to exhaust the body stores if absorption were to cease entirely.

From this brief outline, a broad etiologic classification of gastrointestinal causes of vitamin B_{12} deficiency can be inferred:

1. Lack of the intrinsic factor.
2. Competition for vitamin B_{12} within the gastrointestinal tract.
3. Failure to absorb vitamin B_{12} because of lesions of the ileum.

The digestion and absorption of folic acid (folate) differ considerably from those of vitamin B_{12}. A normal daily American diet contains approximately 1000 μg of folic acid, from 5 to 10 percent of which is absorbed.[11] This absorption takes place in the proximal jejunum and is probably an active process;[12] however, no mechanism comparable to the vitamin B_{12}-intrinsic factor reaction is involved. Although folic acid is widely distributed among foodstuffs, the body stores may be depleted in from three to six months; thus, dietary deficiency of folic acid is much more common than dietary deficiency of vitamin B_{12}.[13] The relationship between gastrointestinal disease and folic acid deficiency is complicated by the fact that folic acid deficiency itself causes intestinal lesions.[13] Thus it is necessary to include nutritional folic acid deficiency in a classification of gastrointestinal disorders associated with such deficiency. A broad classification of the gastrointestinal disorders associated with folic acid deficiency is as follows:

1. Dietary deficiency of folic acid.
2. Competition for folic acid in the gastrointestinal lumen.
3. Failure to absorb folic acid because of lesions of the small intestine.

Deficiencies of vitamin B_{12} and folic acid not infrequently coexist, particularly when there is either widespread disease of the small intestine, or bacterial competition for the two nutrients.

Clinical Application

A. *Vitamin B_{12} deficiency.*

1. Intrinsic factor deficiency.

a. Addisonian pernicious anemia.

The essential defect in pernicious anemia is the lack of production of the intrinsic factor, associated with atrophic gastritis or gastric atrophy. Failure of the stomach to secrete hydrochloric acid is an almost invariable accompaniment. The gastric lesion is not specific for pernicious anemia, since histologically indistinguishable lesions are not invariably associated with reduced intrinsic factor secretion.[14] Recent evidence suggests that pernicious anemia may be a manifestation of an auto-immune process, possibly on a hereditary basis.[5, 14-16] Parietal cell antibodies have been demonstrated by immunofluorescent technics in the serum of approximately 95 percent of patients with pernicious anemia.[17] Antibodies to intrinsic factor have also been reported; however, these occur in only from 40 to 57 percent of patients.[5,15] The parietal cell antibody is also found in the serum of patients who have atrophic gastritis but who do not have overt pernicious anemia,[14] and it may be possible that this represents a 'preanemic' stage of the disease. These patients do not exhibit the intrinsic factor antibody. It is possible to explain the presence of these antibodies on the basis of the 'hidden-antigen' theory that suggests that damage to the mucosa of the stomach may release antigenic material that is 'foreign' to the antibody-forming tissues and acts as a stimulus to the formation of parietal cells and intrinsic factor antibodies.[11,89] Whether this leads to the development of atrophic gastritis with subsequent intrinsic factor deficiency, or merely perpetuates the gastric lesion, is not known.

The association of pernicious anemia with thyroid disease is well documented. Indeed, parietal cell antibodies have been found in the serum of patients with myxedema and Hashimoto's thyroiditis, and, conversely, thyroid antibodies have been found in the serum of patients with pernicious anemia.[14,15,20,21] There is some histologic similarity among the lesions found in these various diseases, and this fact has been used as further evidence in favor of the theory that they are of an auto-immune origin.[15,22]

Although pernicious anemia seldom occurs under the age of 40 years, it may on a rare occasion occur in childhood. There are two forms of childhood pernicious anemia.[23] In one form, a selective lack of the intrinsic factor secretion exists, unassociated with achlorhydria or any histologic gastric lesion. Parietal cell and intrinsic factor antibodies are not found in this type of anemia, which appears to be an inborn error of metabolism unrelated to addisonian pernicious anemia. The other form of pernicious anemia seen in children is indistinguishable from that seen in adults. There is considerable evidence to suggest that pernicious anemia, gastric atrophy, and gastric carcinoma occur more frequently in patients of blood group A than in those of any other blood group.[24,25]

b. Total gastrectomy

An inevitable sequel to microscopically proved total gastrectomy is a megaloblastic anemia indistinguishable from pernicious anemia, occurring as a result of the removal of the source of the intrinsic factor.[26] This complication develops in from two to seven years postoperatively regardless of the reason for the surgical procedure or the type of reconstruction performed. The interval

corresponds with the time required to exhaust the body stores of vitamin B_{12}.

c. Subtotal gastrectomy

Anemia develops in from 20 to 56 percent of patients who have undergone partial gastrectomy.[27-30] In the majority of patients the anemia is attributable to iron deficiency, but megaloblastic anemia has been reported in increasing numbers after proximal subtotal gastrectomy[27] but in only from 1 to 4 percent of patients who have undergone distal subtotal gastrectomy.[27,30]

Deller and Witts[28] and Pedersen and associates[31] pointed out that examination of the peripheral blood smear may be an unreliable measure of vitamin B_{12} deficiency in the anemia after partial gastrectomy, since the hematologic features of vitamin B_{12} deficiency may be masked by coexisting iron deficiency. Subsequently, Deller and Witts[28] and Hines and associates[30] utilized the more sensitive indices of serum B_{12} and folate levels. These authors found that subnormal levels of serum vitamin B_{12} were more frequently demonstrated after partial gastrectomy for gastric ulcer than for duodenal ulcer. There was no such correlation in the case of folate deficiency. Patients with histologic evidence of chronic diffuse gastritis in the resected segment had a greater incidence of postoperative subnormal levels of serum vitamin B_{12} than did patients with histologically normal gastric mucosa. This difference can be accounted for by a decrease in secretion of the intrinsic factor in the former group. Low serum vitamin B_{12} and folate levels were commonly associated with low serum iron levels. Not surprisingly, iron therapy given to these patients restored the iron content of the bone marrow and increased its megaloblastic features, but failed to correct the anemia. All patients in this series with low serum vitamin B_{12} levels required parenteral administration of vitamin B_{12} in order to achieve normal blood hemoglobin levels.

The pathogenesis of vitamin B_{12} deficiency that may, on rare occasions, develop after partial gastrectomy, appears to be the impairment of secretion of the intrinsic factor.

2. Competition for vitamin B_{12} within the gastrointestinal tract.

Two disorders are within this group: first, the "blind-loop" syndrome in which bacteria in the gastrointestinal tract compete for the available vitamin B_{12}; and secondly, infestation by the fish tapeworm (Diphyllobothrium latum). In both these conditions, absorption of vitamin B_{12} is impaired despite the presence of an adequate amount of the intrinsic factor. Normal absorption of vitamin B_{12} is restored after eradication of the organisms.

a. Blind-loop syndrome

Megaloblastic anemia arising in the blind-loop syndrome is usually due to vitamin B_{12} deficiency. It may be found in patients with surgically formed blind loops after partial gastrectomy of the Polya or of the Billroth II-Hofmeister type, particularly if there is a long afferent loop.[30,32] Diverticula of the jejunum may be associated with megaloblastic anemia and may have been associated with the development of abnormal bacterial flora thought to compete with the host for vitamin B_{12}.[33,34] Strictures of the small intestine, internal fistulas, and other lesions are less common causes of this syndrome.[35,36]

Normally the small intestine is virtually free of bacteria, but when stasis occurs, bacteria are able to proliferate.[37,38] Thus, intestinal stasis is the hallmark of this syndrome, although other factors such as impaired blood flow to the intestine may play a part in permitting growth of organisms. The coliform group of organisms is most frequently found in the stagnant region.[39] Although steatorrhea may on occasions be associated with the blind-loop syn-

drome, there is little doubt that the vitamin B_{12} lack results from competition for the vitamin or its inhibition by the organisms themselves. This reduces the quantity of vitamin B_{12} which reaches the distal ileum, and hence the amount available for absorption. Although the competition theory has received the widest attention, other etiologic factors may be involved. These include the possibility that "toxic" substances elaborated by bacteria or other organisms may interfere with vitamin B_{12} absorption, and that by altering the pH in the jejunum these organisms may render unstable the vitamin B_{12}-intrinsic factor complex.[33] Treatment with oral broad-spectrum antibiotics will correct the deficiency,[30,33,36,37,39] a fact that lends weight to the theory of bacterial competition.

b. Diphyllobothrium latum infestation

Megaloblastic anemia due to the fish tapeworm is rare in the United States. However, occasional cases have been reported from the Great Lakes region. In Finland it has been estimated that 20 percent of the population harbors the organism, and, of these, megaloblastic anemia develops in from 1 to 3 percent.[40] Megaloblastic anemia occurs only when there is massive infestation of the proximal portions of the small intestine.[41] Uptake of vitamin B_{12} by the parasite has been found, and the anemia is apparently due to competition with the host for the available vitamin B_{12}.

3. Failure to absorb vitamin B_{11} due to lesions of the mucosa of the small intestine.

a. Tropical sprue

Tropical sprue, a malabsorptive disease affecting the entire small bowel, is endemic to the Caribbean countries, the Indian subcontinent, and southeast Asia. Megaloblastic anemia may be found in as many as 72 percent of patients in the advanced stages of the disease.[42] The reported incidence of megaloblastic anemia due to vitamin B_{12} deficiency ranges from rare to predominant and it may or may not be associated with folic acid deficiency. These variations appear to be directly related to geographic differences and to the acuteness of the disease.[42-45] Vitamin B_{12} deficiency has been reported to be the predominant cause of megaloblastic anemia in patients with tropical sprue in Haiti, but a rare cause in patients with acute tropical sprue in Singapore. The mechanism of vitamin B_{12} malabsorption is not clearly understood, but it is perhaps related to villous atrophy that involves the mucosa of the entire small bowel, including the ileum.[46,47] In therapy, pharmacologic doses of vitamin B_{12} or of folic acid, or the administration of tetracycline, will usually induce clinical remission and increase intestinal absorption of the nutrient agents.[42,46,48-50]

b. Gluten-induced enteropathy

Gluten-induced enteropathy, like tropical sprue, is a disease of the small-bowel mucosa, characterized by villous atrophy related to an intolerance to gluten in the diet.[51] Megaloblastic anemia due to vitamin B_{12} deficiency is an infrequent complication of this condition among adults. However, decreased serum vitamin B_{12} levels are not unusual.[52,53] No abnormality of the intrinsic factor secretion has been found, and vitamin B_{12} absorption returns to normal when gluten is removed from the diet. Serum vitamin B_{12} levels are generally normal among children with this disease, and the cause of megaloblastic anemia in the juvenile form is usually related to folic acid deficiency.[54]

Recent studies[55-57] have shown that severe vitamin B_{12} deficiency affects the epithelium of the small intestine, with resultant mucosal changes, which are thought to be the result of long-standing vitamin B_{12} deficiency

and not the cause of a vitamin B_{12} absorptive defect.

c. Regional enteritis

The most common cause of specifically impaired absorption of vitamin B_{12} is regional enteritis with involvement of the terminal ileum.[12,58] However, megaloblastic anemia becomes a virtual certainty when extensive resection of the ileum has been performed.[3,59]

d. Small-bowel resection

Decreased absorption of vitamin B_{12} occurs after resection or after bypass reconstruction of the distal ileum.[3,60] Vitamin B_{12} deficiency invariably develops when more than six to eight feet of terminal ileum is resected or bypassed.[3] Megaloblastic anemia and other manifestations of vitamin B_{12} deficiency occur from one and one-half to six years after operation, and appear to be directly related to loss of the absorptive site of vitamin B_{12}.

B. *Folic acid (folate) deficiency*

Megaloblastic anemia due to folate deficiency may be caused by gastrointestinal disorders that affect the jejunum, as well as by nutritional or dietary lack. Folic acid is absorbed primarily in the jejunum, and it appears that the major mechanisms in folic acid deficiency are malabsorption due to abnormal jejunal mucosa, or dietary lack. Additionally, there are mechanisms of folic acid deficiency which are poorly understood, such as that occurring in late pregnancy,[61] and that associated with anticonvulsive drug therapy.[62,63] In the former instance, a conditioned lack may result from preferential fetal uptake of folic acid in a mother whose intake is borderline. In the latter instance it is postulated that there is competition or inhibition of folic acid.

1. Nutritional or dietary lack.

Folic acid deficiency with resultant megaloblastic anemia may occur in almost any form of severe nutritional deficiency, and it is particularly common in the nutritional deficit associated with alcoholic cirrhosis of the liver.[64,65]

2. Failure to absorb folic acid because of lesions of the small intestine.

a. Partial gastrectomy

Megaloblastic anemia due to folic acid deficiency resulting from partial gastrectomy has been reported only rarely.[29,30,66,67] Anemia associated with combined iron and folic acid deficiency (on the basis of bypass of the proximal jejunum or rapid passage of foodstuff through the absorptive area) and normal serum vitamin B_{12} levels is a more common finding.[30] This anemia may demonstrate morphologic characteristics both of iron deficiency and of folic acid deficiency ("dimorphic" anemia) with resultant hypochromic microcytic cells in association with macrocytic erythrocytes and a megaloblastic bone marrow. Iron therapy alone will often afford temporary alleviation of the anemia, but the morphologic picture of folic acid deficiency and low serum folate levels remains.[30] The pathogenesis of folic acid deficiency after partial gastrectomy is not clear; poor dietary intake may sometimes be the cause. There also seems to be a relationship between iron deficiency and folic acid deficiency, perhaps related to jejunal malabsorption of both of these nutrient agents.

b. Tropical sprue.

The incidence of megaloblastic anemia secondary to folic acid deficiency may be quite high in tropical sprue, and in the acute form of the disease folic acid deficiency appears to be the primary cause.[42,43] Although the mucosal abnormality is presumably related to the malabsorption of folic acid, the

exact nature of the defect is not known.[47] Involvement of the ileal mucosa may account for vitamin B_{12} malabsorption. Since the intestinal lesions and the low serum folate levels respond to oral tetracycline therapy, the belief is no longer held that folic acid deficiency is itself the cause of tropical sprue.[46,47,50]

c. Gluten-induced enteropathy.

Folic acid absorption may be severely depressed in gluten-induced enteropathy, because of the jejunal abnormality, and folic acid deficiency is the most common cause of megaloblastic anemia in the adult form of this disease.[52] Although serum vitamin B_{12} levels may be somewhat decreased, overt vitamin B_{12} deficiency is infrequent. In the juvenile form of gluten-induced enteropathy, megaloblastic anemia due to folic acid deficiency is constant, and serum vitamin B_{12} levels are normal.[54] The severity of impairment of folic acid absorption appears to correlate well with the degree of jejunal villous atrophy.[68,69] The return of folic acid absorption to normal levels and the remission of anemia occur with gluten restriction in the diet.[48,52]

d. Blind-loop syndrome.

Folic acid deficiency as the sole cause of megaloblastic anemia is extremely rare in the "blind-loop" syndrome. Folic acid deficiency has been found in association with jejunal diverticulosis (and megaloblastic anemia), but this appears to be a minor contributing factor to the megaloblastic anemia that may be present.

e. Regional enteritis.

Folic acid malabsorption may occur in inflammatory disease of the small intestine, with jejunal involvement, and decreased folate levels may be found in the serum.[12] However, megaloblastic anemia solely due to folate deficiency is rare in regional enteritis, since involvement of the ileum is much more frequent than that of the jejunum.

Summary

Gastrointestinal causes of megaloblastic anemia are deficiencies of absorption of vitamin B_{12} and/or folic acid. Vitamin B_{12} deficiency may result from: failure of secretion of the intrinsic factor; mucosal abnormalities in the terminal ileum which prevent vitamin B_{12} absorption; competition for vitamin B_{12} by organism in the small intestine. Folic acid deficiency may result from dietary lack or mucosal abnormalities of the jejunum which prevent folic acid absorption.

Techniques

The Feeding Cervical Esophagostomy

An Alternative to Prolonged Intravenous, Nasogastric, and Gastrostomy Feeding

MANY PATIENTS who are unable to take food orally nevertheless maintain essentially normal intestinal motility and absorption. Conditions that interfere with oral sustenance include neoplasms of the oropharyngeal region, severe maxillofacial trauma, neurologic conditions, and miscellaneous illnesses that depress the appetite and alter the states of consciousness. Methods of sustaining a patient who cannot eat food are by nasogastric intubation, by intravenous feedings, by transperitoneal gastrostomy, and by cervical esophagostomy.

During the last five years at the Cleveland Clinic Hospital, cervical esophagostomy has been created in many patients who require extraoral sustenance for more than a week. This procedure was initially described by Klopp,[1] who performed it for the treatment of obstructive esophageal carcinoma. Ketcham and Smith[2] subsequently demonstrated the effectiveness of the cervical esophagostomy in a large number of patients. Early experience with this procedure at the Cleveland Clinic was reported[3] in 1964. Since that report, feeding cervical esophagostomy has been performed on 86 patients; it has proved beneficial in a great diversity of conditions. The operation has been without significant early or late complications. Anesthesia for this procedure may be either local or general. A brief description of the technic follows.

A nasogastric tube simplifies identification of the esophagus. An incision is made about 3 cm above and parallel to the clavicle (Figure 1A). The sternocleidomastoid muscle is retracted laterally (Figure 1B), and with blunt dissection the thyrolaryngeal structures are separated from those of the carotid sheath. In this fashion the bodies of the lower cervical vertebrae are approached (Figure 1 C), and the esophagus, lying just anterior to them, is gently mobilized (Figure 1 D). Traction sutures secure the esophagus while an opening is made (Figure 1 E). The nasogastric tube is withdrawn from the nose, facilitating passage of a tube through the esophagostomy (Figure 1 F), and the wound is loosely closed with one or two skin sutures. The feeding tube is anchored securely to the skin and serves as a wound drain.

Within one week the esophagostomy tract has become well established, and the tube may be removed and replaced. Rapid obliteration of the tract occurs after removal of the tube.

Comments

Cervical esophagostomy provides an easy, safe method of gavage feeding. For prolonged use it surpasses nasogastric intubation; the tube is away from the patient's face, cricoiditis is not a complication, and there is no nasal dis-

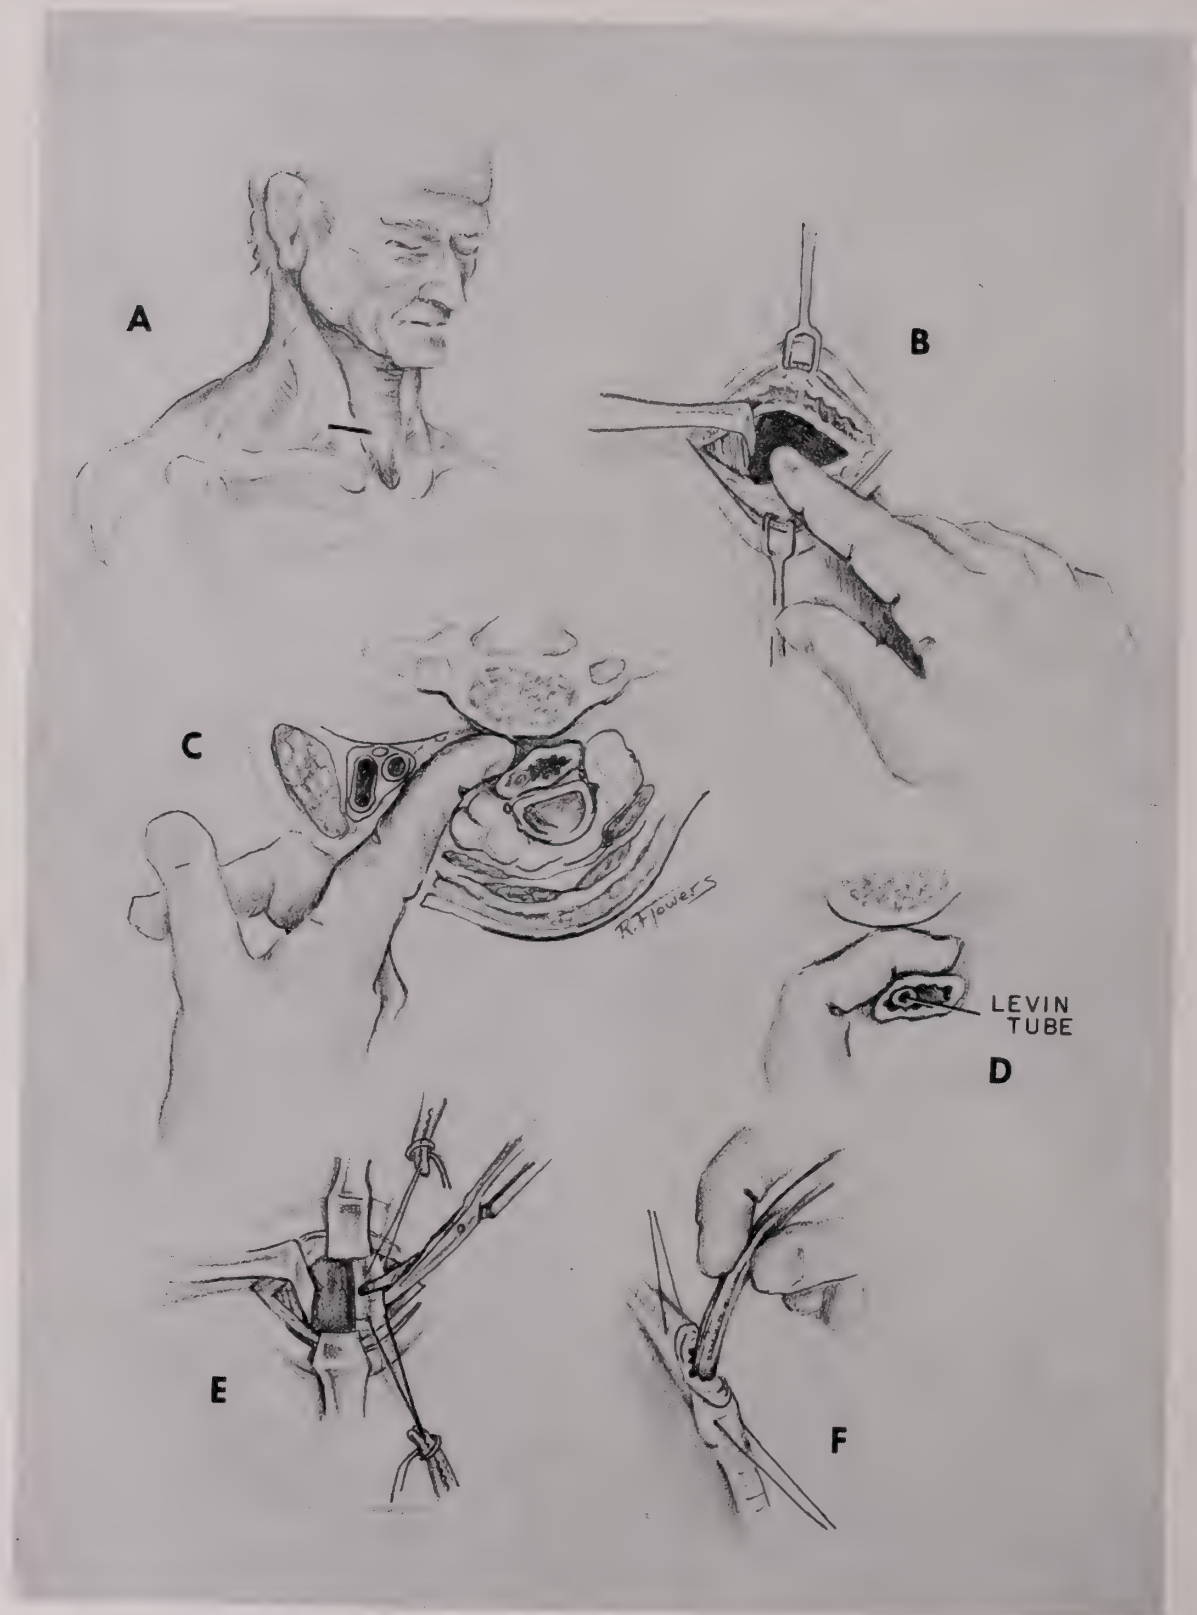

Fig. 1—Sketches showing technic of esophagostomy. comfort. It is a safer, simpler procedure than the gastrostomy which, in time, may leak irritating juices on the abdominal skin. Reflux is no problem in cervical esophagostomy where the advantages are simplicity of technic, effectiveness, and comfort of the patient.

Doctor-Patient Relationship

Historians sentimentalize the practical values of ancient medicine. One scans the pages of Hippocrates in vain for any treatments of specific value. The pages of medical history read like the log of an old-fashioned ocean voyage, in which it is noted that on such a day a whale spouted, on such a day a flying fish was sighted, or a bit of driftwood, but in which no mention is made of the huge prevailing fact that what was constantly seen day by day, almost to the exclusion of other sights, was the unending green waste of water. And this inevitably circumambient ocean is, by analogy, in medical history the "personal relationship between doctor and patient."*

*W. R. Houston in Richard M. Magraw: Ferment in Medicine, 1966.

The Progress Notes of Hippocrates

In Larissa,* a young unmarried woman was seized with a fever of the acute and ardent type; insomnolency, thirst; tongue sooty and dry; urine of a good color, but thin. On the second, in an uneasy state, did not sleep. On the third, alvine discharges copious, watery, and greenish, and on the following days passed such with relief. On the fourth, passed a small quantity of thin urine, having substances floating towards its surface, which did not subside; was delirous towards night. On the sixth, a great hemorrhage from the nose; a chill, with a copious and hot sweat all over; aprexia, had a crisis. In the fever, and when it had passed the crisis, the menses took place for the first time, for she was a young woman. Throughout she was oppressed with nausea, and rigors; redness of the face; pain of the eyes; heaviness of the head; she had no relapse, but the fever came to a crisis. The pains were on the even days.†

Editor's Note: Ovulation pain and vicarious menstruation.

Tandearil® in Osteoarthritis
oxyphenbutazone

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.
Warning: Tandearil is an analog of phenylbutazone; sensitive patients may be cross-reactive. If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Persistent or severe dyspepsia may indicate peptic ulcer; perform upper gastrointestinal x-ray diagnostic tests if drug is continued. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with caution in the first trimester of pregnancy and in patients with thyroid disease.
Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia), sudden weight gain (water retention), skin reactions, black or tarry stools or other evidence of intestinal hemorrhage occur. Make complete blood counts at weekly intervals during early therapy and at 2-week intervals thereafter. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.
Adverse Reactions: The more common are nausea and edema. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension, the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reacti-

"Pain Break" for an osteoarthritic.

Tandearil can usually ease it.

At 46, her knees still look good on the outside. But inside, there may be the familiar picture of osteoarthritis.

If aspirin doesn't help, Tandearil often will. Pain and stiffness begin to ease up in 3 or 4 days. You can often maintain response with a daily dose of only 1 or 2 tablets.

Of course, Tandearil is not for every osteoarthritic. Select your patients carefully and follow them in line with the Contraindications, Precautions, Warning, and Adverse Reactions listed below.

But for many aspirin-stubborn osteoarthritics, let Tandearil ease the unwelcome pain breaks of osteoarthritis.

Tandearil®
oxyphenbutazone

vate a latent peptic ulcer. The patient should be instructed to take doses immediately after meals or with milk to minimize gastric upset. Drug rash occasionally occurs. If it does, promptly discontinue the drug. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis) or a generalized allergic reaction similar to a serum sickness syndrome may occur and require permanent withdrawal of medication. Agranulocytosis can occur suddenly in spite of regular, repeated normal white counts. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, hypersensitivity, angiitis, pericarditis and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

For complete details, please see full Prescribing Information.

Geigy

Dosage in Osteoarthritis: Initial: 3 to 6 tablets daily in divided doses. Usually unnecessary to exceed 4 tablets daily. A trial period of one week is considered adequate to determine the therapeutic effect of the drug. Maintenance: Effective level often achieved with 1 or 2 tablets daily, should not exceed 4 tablets daily. In selecting appropriate dosage in any specific case, consideration should be given to the patient's weight, general health, age and other factors influencing drug response. Availability: Tan, round, sugar-coated tablets of 100 mg. in bottles of 100 and 1000.

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

Abstracts, Briefs and Commentaries

GAUCHER'S DISEASE

Twenty cases of Gaucher's disease are reported with particular emphasis on the skeletal manifestations of the disease. A summary of all of the cases is presented as well as many illustrative roentgenograms.

The femur was usually the first, as well as the most frequent, bone to be affected by Gaucher's disease. All patients showed roentgenographic changes in the femoral head or diaphysis. Pathologic fractures of the proximal femur occurred in eight femora in seven patients. Healing was delayed. Avascular necrosis of the femoral head was the most common symptomatic skeletal lesion and occurred in 15 patients, bilaterally in six children and in three adults. The necrosis healed in one seven-year-old child, but recurred at the age of 19 years. Three patients had necrosis of the humeral head—two bilaterally. Other bones affected with the Gaucher's process were radius, ulna, tibia, talus, skull, and vertebral bodies. The thrombocytopenia improved after splenectomy; however, splenectomy did not appear to influence the onset or progression of skeletal manifestations of Gaucher's disease. Roentgentherapy was of little value and may have had adverse affects in the treatment of this disease. The effectiveness of nonweight bearing for treatment of necrosis of the femoral head in children could not be determined, but may result in a more congruous head. In adults, early replacement with a long-stem prosthesis was the preferred treatment for necrosis of the femoral head. Other reconstructive surgical procedures were of benefit. The authors caution that meticulous attention to the prevention of infection and hemorrhage is essential.

Comment. This is a scholarly and detailed study of the orthopedic problems related to Gaucher's disease, and is a notable contribution to the scant knowledge heretofore available about this unusual disease.

VITAMIN D

For more than 40 years it has been known that vitamin D is needed for proper growth and prevention of rickets in humans. Vitamin D has been made easily available as inexpensive vitamin supplements, in the enrichment of milk and other foodstuffs, and consequently rickets is now a rare disorder.

It is also known that vitamin D is dangerous in extremely high doses. It was originally thought that the margin of safety between the daily requirement and the toxic dosage was wide, but this range has been challenged. In 1952, reports from Great Britain and from Switzerland implied that vitamin D is the etiologic agent of unexplained hypercalcemia, and since then doses in excess of 400 units per day have been questioned.

In 1963 the American Academy of Pediatrics Committee on Nutrition published a report on the present thought in regard to vitamin D requirements and the possibility that excessive vitamin D causes idiopathic hypercalcemia. Since then it has become apparent that the severe form of hypercalcemia has its inception in utero. The later normocalcemic phase of the severe infantile form has been recognized in older children and is a severely debilitating condition. In 1965 the Committee on Nutrition recommended and amplified the following procedures: (1) continuance of the enrichment of all types of milk with vitamin D at the level of 400 I.U. per quart; (2) discontinuance of vitamin D supplements in all other foodstuffs; (3) adjustment of all vitamin D supplements to contain 400 I.U. per recommended daily dose; (4) assessment by the physician of the patient's dietary intake of vitamin D before he prescribes specific vitamin D supplements.

Your Health—Mr. President

In a review of the actual causes of death among the first 30 Presidents, seven died of cerebral hemorrhage—John Quincy Adams, John Tyler, Millard Fillmore, Andrew Johnson, Chester Arthur, Warren Harding, and Franklin Roosevelt.

The next largest group consists of the five Presidents who died of coronary disease—James Madison, Rutherford Hayes, Grover Cleveand, Theodore Roosevelt, and Calvin Coolidge.

Four Presidents died of congestive heart failure—John Adams, James Monroe, Martin Van Buren, and William Howard Taft.

Pneumonia caused the death of three Presidents—William Henry Harrison, James Buchanan, and Benjamin Harrison.

Chronic intestinal infection claimed the lives of three Presidents—Thomas Jefferson, James Polk, and Zachary Taylor.

Of the remaining Presidents, Franklin Pierce died of cirrhosis of the liver. The majority of the evidence points to pulmonary tuberculosis as the cause of Andrew Jackson's death. Ulysses Grant died of cancer of the tongue, tonsil, and larynx, and Woodrow Wilson of cerebral thrombosis. George Washington died of acute streptococcic pharyngitis.

The final three Presidents, Abraham Lincoln, James Garfield, and William McKinley, died by assassination, in each case from gunshot wounds.*

*Karl C. Wold, M.D.: Mr. President—How Is Your Health?

Now . . . a new
alternate salicylate product
from Warren-Teed

Magan®
(magnesium salicylate, W-T)

magan®

an alternate salicylate

particularly offered for the management of those chronic arthritic and rheumatic patients with gastrointestinal intolerance to aspirin and other salicylates

pain relief comparable to aspirin

Magan may provide effective salicylate therapy for a substantial number of your patients who cannot tolerate other salicylates because of gastrointestinal irritation.

Magnesium salicylate is recognized as a safe and effective alternate to aspirin. A controlled clinical study showed Magan to be not significantly different from aspirin as an analgesic in the treatment of arthritic patients.[1]

Reports from a private practice experience study indicate that Magan was tolerated by a high percentage of patients judged by their physicians to be unable to take aspirin or other salicylates due to gastrointestinal intolerance.[2]

1. Stern, S.B.: Med. Times, Oct. 1967
2. Reports on 1200 patients, data in files, Warren-Teed Pharmaceuticals, Inc. 1966

(See next page for prescribing information)

A different salicylate structure—
with no coating, no buffering
and it is sodium free

magan®
(Magnesium Salicylate, W-T)

microphotograph of magnesium salicylate crystals

Composition: Each orange-colored compressed tablet contains 5 grains (approximately 325 mg.) of magnesium salicylate, W-T (salicylic acid equivalent 75%).

Actions, Indications, Uses: The analgesic, anti-inflammatory, and antipyretic effects of MAGAN are similar to those of aspirin and other salicylates. Accordingly, MAGAN is indicated for the treatment of rheumatoid arthritis, osteoarthritis, nonarticular rheumatism such as bursitis, painful-shoulder syndrome, tendosynovitis, fibrositis, and other musculoskeletal disorders. The drug is also useful for the symptomatic relief of pain, aches, and discomfort of headache, neuralgia, minor injuries, dysmenorrhea, common cold and other minor infections of the respiratory tract. MAGAN (Magnesium Salicylate) may be tolerated by some persons intolerant to aspirin by reason of gastrointestinal irritation.

Contraindications: Because of the danger of hypermagnesemia, MAGAN is contraindicated in cases involving advanced chronic renal insufficiency. MAGAN, as other salicylates, may counteract the effect of uricosuric agents, and should not be prescribed for patients on such drugs.

Warning: As with all salicylates, high dosages of MAGAN should be avoided entirely or administered with caution to patients with liver damage, preexisting hypoprothrombinemia, vitamin K deficiency, and before surgery.

Adverse Reactions and Precautions: The same precautions applicable to salicylate therapy in general should be followed in prescribing MAGAN. Appropriate precautions should be taken in prescribing MAGAN for persons known to be sensitive to salicylates. If reaction develops, drug should be discontinued. Dosages of anticoagulants should be reduced with the administration of high dosage levels of MAGAN. *Impaired Renal Function:* Appropriate precautions should be taken in administering MAGAN to patients with any impairment of renal function including discontinuing other drugs containing magnesium and monitoring serum magnesium levels particularly if dosage levels of MAGAN are high. *Salicylate Poisoning:* Symptoms of salicylism, resulting from high doses of MAGAN, can be expected to resemble closely in character and intensity those associated with aspirin poisoning. These range from dizziness, drowsiness and ringing in the ears to vertigo, convulsions, coma and hypokalemia. Salicylate poisoning can be treated by intravenous fluids with sodium bicarbonate or lactate and potassium supplementation. In very severe cases, hemodialysis may be necessary. Vitamin K, 5-20 mg. orally or slowly i.v., usually restores the prothrombin time to normal.

Dosage: Adults 1 or 2 tablets every 4 hours as required with a full glass of water. In arthritis and other rheumatic conditions, higher doses may be used at the discretion of the physician. The experience with MAGAN in children is limited. The drug should not be used, therefore, for patients below 12 years until indications for use and dosage have been established.

How Supplied: Bottles of 250 and 1000 tablets.

Treatment of Cancer of the Breast

Biological Considerations*

GEORGE CRILE, Jr., M.D.†
Cleveland, Ohio

THE TREATMENT of cancer of the breast is a subject that stands on the frontier of medical knowledge where little of the truth is as yet known. Although we know little about cancer, several facts are apparent. One of the most disheartening of these is our world-wide failure to control the age-adjusted death rate from cancer per hundred thousand persons. Perhaps we have gained in regard to a few specific types of cancer, but in regard to most of the major cancers—cancer of the breast is as good an example as any—the death rate remains constant. This, despite efforts of surgeons to perform wider excisions and more radical procedures, and despite better than ever radiation therapy. The fact of there being no change in the death rate, highlights a paradox: in regard to almost any type of cancer studied, there has been progressive improvement in the cure rate. What is the explanation?

It is impossible to reconcile a rising cure rate with a constant death rate unless a third factor is introduced. This is the recognition rate, and in cancer it is rising rapidly. More frequent diagnosis of cancer leads to the inclusion of many cancers of borderline malignancy, such as papillary carcinomas of the thyroid, rectal polypoid carcinomas, intraductal cancers of the breast, prostatic microcarcinomas, and in-situ cancer of the uterine cervix. These and many other types of low-grade cancer treated successfully increase the five-year cure rate. Earlier treatment of cancers that ultimately prove fatal also increases the five-year cure rate by enabling a higher proportion of patients to survive for five years, even though the patients die within a year or so later. But neither of these factors influences the death rate per 100,000 persons. As McKinnon[1] has said: "We do not alter the death rate from cancer by curing cancers that would not have been fatal even if untreated." Unless the now-fatal cancers are

*Taken from "A Biological Consideration of Treatment of Breast Cancer," by George Crile, Jr., published by Charles C. Thomas, Publisher, Springfield, Illinois, 1967, by permission of the publisher.

†Department of General Surgery, The Cleveland Clinic Foundation, Cleveland, Ohio.

treated with improved methods, the death rate per 100,000 persons will remain unchanged. That is our problem.

McWhirter[2] has shown that if a cancer starts as a single cell it can be estimated that it would take 20 divisions of that cell and all its descendants to make a mass 1 mm in diameter. Thirty cell divisions would be required to make a mass 1 cm in diameter: forty divisions and the tumor would weigh more than one pound; fifty divisions and it would weigh more than 1000 pounds. The growth of cancer follows an exponential curve that at first rises slowly and then heads skyward as the doubling goes on. A tumor that grows exceedingly fast may double its size once a month. A slowly growing tumor, like a scirrhous cancer of the breast, may not double its size in a year. If we correlate these rates of doubling with the number of cell divisions that are required to make a mass 1 cm in diameter, it is clear that a rapidly growing tumor, that doubles its size once a month, must have been present for at least 30 months before it reached the size of 1 cm. A slowly growing tumor that doubles at the rate of once a year must have been present for 30 years or longer to have attained that size. The tiny scirrhous cancer discovered in the breast of a 70-year-old woman may have started growing when she was 30 or 40 years old. But from the time the tumor 1 cm in diameter is discovered, it might take less than 10 years for it to grow to weigh more than a pound. In view of the long history of such a cancer, and the probability that during much of its life history it was capable of metastasizing, it is small wonder that earlier treatment has done little to control the ultimate death rate from such cancers.

Until we know more about the factors that control the spread of cancer, we should not generalize about the subject of cancer. At present there is no scientific basis upon which anyone is justified in advocating simple mastectomy, radical mastectomy, ultraradical mastectomy, or irradiation therapy as the single or even the chief method of treatment of cancer of the breast. There may be a place for all of these types of treatment, for, just as there are three types of cancer of the skin—basal cell, squamous cell, and melanoma, so there may be at least three biologic types of cancer of the breast. If so, each may respond best to its own type of treatment. The challenge to the surgeon is to try to find a way to distinguish each of these biologic types from the others. Individualization deserves more emphasis than it has been given in our cancer clinics in recent years.

Although our understanding of the factors that cause cancer has increased a great deal, the clinical approach to the problems of treatment has changed little. In most cases, adequate operations performed as early as possible still seem to afford the best chances of cure. Radiation applied to localized and radiosensitive lesions is often equally successful.

Genuine advances have been made in endocrine control of endocrine-dependent tumors. Chemotherapy is used for a few types of cancer, usually for palliation only. Although immunologic methods of controlling cancer have not as yet been successful, possibly in the future this line of attack will be more effective than any of the new, established methods. Moreover, there may be merit in attempting to preserve and enhance what natural immunity the host may have against this tumor.

The most hopeful aspect of the cancer problem is our increasing knowledge of the factors that control differentiation, mutation, and growth. We now recognize the cell's ability to adapt its enzyme system to environmental changes; we recognize that there are factors in embryonic life which regulate cell differentiation; we are beginning to study the interplay of the local and the systemic factors that control cellular growth. These advances and an increasing understanding of the genetic mechanism of the normal cell make it likely that soon we shall have better understanding and more effective treatments of cancer.

One of the most promising areas for research is study of the local factors that control normal cellular growth. If the chemical substances that control the growth of each type of cell could be identified and made available, it is likely that they could be used to prevent the development of many cancers, and to control the growth of these cancer cells that have not attained complete autonomy of growth.

Our thinking about cancer has come a long way. At least we can view it not as a demon to be exorcised, but rather, in its true biologic

perspective as an unwanted phenomenon of growth. Progress comes through understanding the ways of nature rather than from trying to bend them to our will. Only after we understand the factors that control the growth of normal cells will the problems of cancer be solved.

Epilepsy and the Moon

The medical theories prevailing in eighteenth century United States and their formidable therapeutic application are well illustrated by the treatment of an epileptic Negro slave by a Virginia physician, in a manner which ample evidence indicates was not unusual:

"When first he came to me I put him on a course of Cumabarine Medicines. I bled him, in the fit, vomited him afterwards and . . . gave him aorthrementics and mercurial purges. All this seemed to do no good. I therefore Resolved to give him a shock from the two Glass Spheres fixed to an Electric Machine, but before I could get it completely fixed I drew a blister on the scalp behind—upon the Occupit, dressed it according to Art and made it perpetual, at the same time putting him under a different course of Medicines than had been tried before. The Blister ran Bountifully for a while; but drying, I laid another upon the nape with an Intent to Stimulate a Branch of a Considerable Nerve Called par Vagum which in that part Lays Something Superficial, continuing the Medicines with little Alteration. This succeeded and the next Change of the Moon expecting the fit, as usual, he missed them. The Medicine has been continued and he has missed the fits this last full moon again. The Blister is almost dry but I intend if the fellow stays with me to draw a fresh one. It is something remarkable that the fits has Usually returned when the Moon was in the Sign Capricorn Even When it was a week before or after the full or change."*

Incubation

I began practicing medicine at the age of eight, on the cat. I mixed weeds with chopped-up angleworms and, adding a little water, put the infernal mess in green glass bottles, letting it stand in the hot sun of the Middle West for several days until the mixture was ripe.

I suppose nothing ever had a more unholy smell; that was my only standard of medical potency. I fed little spoonsful of it to my gray cat, who yowled and fought like a child taking castor oil. Then I spent hours holding it and loving it, keeping away from the house and the family till its paroxysms were abated.

Every day of my life I looked forward to being a doctor. I never knew why, and I don't remember that the reasons even interested me.*

Diarrhea

TROCINATE® 400 MG.

BRAND THIPHENAMIL HCl.

The relief received from the first Trocinate 400 mg. tablet is so prompt that the discomfort of diarrhea ceases to be a bother. May be repeated every four hours.

Upon request, a supply of Trocinate 400 mg. with literature will be sent to physicians for their personal use.

Save him from RHEUMATIC FEVER

Here are two ways:

1. If your child has a bad sore throat, don't wait – it might be "strep." Call your doctor. Treatment of "strep" infections usually can prevent rheumatic fever and the heart damage it sometimes causes.

2. Give to your Heart Fund. Your Heart Fund dollars support research and community service programs which can wipe out rheumatic fever and save thousands of young lives.

GIVE ...
so more will live
HEART FUND

History of Medicine

The Cleveland Clinic Foundation

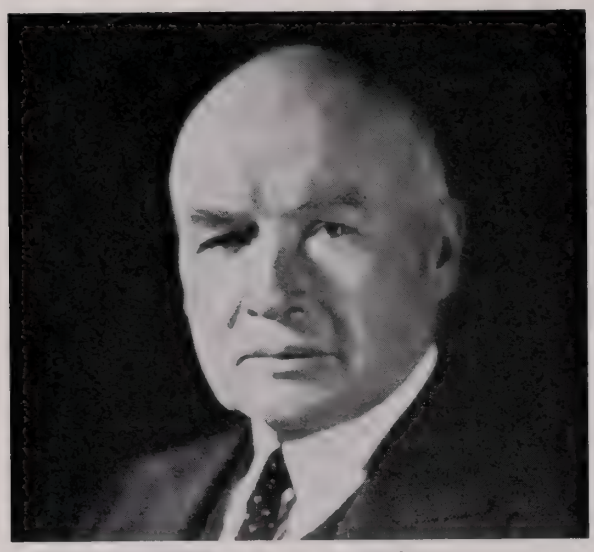
FAY A. LeFEVRE, M.D.*
Cleveland, Ohio

THE CLEVELAND CLINIC opened its doors to patients and began the practice of medicine in February of 1921, incorporated in the State of Ohio as a nonprofit institution. It was founded by four physicians whose medical achievements became known throughout the world—George Crile, M.D.; Frank Emory Bunts, M.D.; William Edgar Lower, M.D.; and John Phillips, M.D. (Figure 1). Doctor Crile, Doctor Bunts, and Doctor Lower had practiced together many years as a "team" before the official opening of the Cleveland Clinic, the original building of which is shown in Figure 2. They believed that the team approach to the practice of medicine would best serve the patient, and that the group practice of medicine would most fully achieve three special goals they set for the Clinic: *Better care of the sick, further study of their problems, more teaching of those who serve* (Figure 3).

A brief mention of the organization and the facilities of the Cleveland Clinic follows.

The Cleveland Clinic Foundation is governed by a Board of Trustees comprised of a group of prominent businessmen and members of the professional staff. A Board of Governors, consisting only of members of the medical staff, is responsible for all medical phases of the Clinic and the Hospital.

The Cleveland Clinic Foundation is comprised of three units: the Cleveland Clinic, the Cleveland Clinic Hospital, and the Division of Research. The Cleveland Clinic Educational Foundation is a separate corporation affiliated with The Cleveland Clinic Foundation. The Cleveland Clinic has four primary medical divisions—Medicine, Surgery, Pathology, Radiology—and each of these divisions is organized into specialty departments. The professional staff number 150 physicians and doctors of philosophy, and 270 fellows and interns who participate in thirty-one educational programs with a view to qualifying as certified specialists. A total of 2500 employees serve as supporting personnel. The physical facilities, composed of buildings, parking lots, and equipment, cover approximately three city blocks on the east side of the city of Cleveland.



*Chairman, Board of Governors, The Cleveland Clinic Foundation.

George Crile, M.D.

Frank E. Bunts, M.D.

William E. Lower, M.D.

John Phillips, M.D.

Fig. 1—The four founders of the Cleveland Clinic

Fig. 2—Original building constituting the Cleveland Clinic in 1921.

The 10-floor Main Clinic Building has in it physicians' offices, examination rooms, laboratories, waiting rooms, business offices, the telephone operators, the Department of Photography, and the Department of Medical Illustration.

The Central Building, with a curved-drive entrance (Figure 4), joins the Main Clinic Building and the Hospital and provides additional space for clinic practice, for research projects, for laboratories, and for business operations; and it has a first-floor automated snack bar. The Cleveland Clinic Pharmacy is across the street from the main entrance and adjoins the largest Clinic parking lot.

The Cleveland Clinic Hospital has 650 beds, 26 operating rooms, and a cafeteria; a tiny, lovely, nondenominational chapel adjoins the lobby and is accessible at all times. The hospital has two unusual features: a five-bed Kidney Dialysis Unit and a Cardiovascular Unit. The Kidney Dialysis Unit is the second one in the United States to use the new method of having the dialyzing solution mixed in a master control room and piped to each patient's bed where it is used for one complete circuit of the patient's blood, then is discarded, and is replaced from the control room. The Cardiovascular Unit is a 39-bed unit that is entirely self-contained, even having its own three operating rooms and radiologic service. It has a 15-bed intensive care section (Figure 5) with all the modern safeguards for the patient, where he remains under close, skilled scrutiny until he is ambulatory and can be transferred to a general medical-surgical nursing floor in the hospital.

For many years research has played an important part in the activities of the Foundation. Time and facilities are provided to members of the professional clinic staff for approved research projects. The majority of the research, however, is conducted by the staff of the Division of Research, which occupies a separate building adjoining the Hospital and the Clinic. The total research group, including full-time members of the staff, Research fellows, and supporting personnel, comprises more than 60 persons. Programmed research is related chiefly to cardiovascular disease, with special interest directed toward hypertension and arteriosclerosis. In addition to the cardiovascular program, research in the area of immunology as it relates

Fig. 5—Intensive care section of the Cardiovascular Unit in the Cleveland Clinic Hospital.

Fig. 6—The Education Building, with auditorium, offices, the Medical Library, and three floors of one-person bedroom studies for fellows and interns.

to organ transplantation is being developed. Every effort is made to relate program research to clinical medicine, resulting in close cooperation between the research and clinical staffs. Financial support for the research programs comes from the Foundation and its endowments, from private foundations, and from the National Heart Institute.

The seven-story Education Building (Figure 6) was completed in 1964: the gift of a grateful patient. In the Education Building is the Bunts Auditorium that seats 272 persons. There, throughout the year, are held fifteen two-day postgraduate seminars on various medical subjects of timely interest. Physicians from all over this country and from Canada attend the meetings. Outstanding guest lecturers are featured on the program along with our own staff physicians.

In the Education Building are the offices of the Director of Education, the Reprint Room, the staff physicians' lounge, offices for emeritus staff members, and six completely equipped seminar rooms. Also in this building are the 15,000-volume Medical Library and the Editorial Department where the *Cleveland Clinic Quarterly* (publication of medical papers written by staff physicians and fellows) is prepared for the printer. The top three floors of the Education Building have 63 one-person bedroom studies for residents and interns; on each floor is a recreational lounge. A closed ramp leads from the fifth floor directly to the sixth floor of the hospital for the convenience of fellows on call.

A guest motel is now under construction across the street from the hospital and will include an indoor swimming pool and a sauna room. A second-floor ramp will connect the two buildings. The motel will have direct access to the facilities of the 150-room Bolton Square Hotel, where patients and their families and many Clinic nurses are housed.

The many modern structures that have met the needs of a growing medical service now surround the North Clinic Building, the Clinic's first building in 1921. A great many changes have taken place in the forty-seven years since the Cleveland Clinic was organized, not only in the development of the physical facilities, but in the training of residents and interns, and in diagnostic and therapeutic technics. In the pre-

ceding pages of this issue of *Minnesota Medicine,* Cleveland Clinic staff members present scientific reports of their clinical experiences, an editorial, and a clinicopathologic conference; and a special section comprises reports by some of our resident physicians.

Speakers' Bureau

It is generally agreed that, ideally, anesthesia should be administered by or under the direct supervision of a physician with training and experience in anesthesiology. But anesthesiology, like many other medical specialties, has such a serious manpower problem that it is not likely that this desirable goal can be achieved in the foreseeable future. Locally, anesthesiologists are in such short supply that their services are directly available in only a small fraction of Minnesota communities. The ultimate responsibilitiy for anesthetic administration therefore often falls wholly upon the patient's family physician who must then delegate it to an assistant—often an individual without medical, training and with limited technical background and experience.

In an effort to furnish interested practitioners with help in this dilemma, the Minnesota Society of Anesthesiologists has established a Speakers' Bureau whose purpose is to provide physician and paramedical groups with authoritative information about anesthesiology and related subjects. A roster of experienced speakers is available for assignment to regional and local programs upon request by a sponsoring group.

The speakers strive primarily to provide solutions to common clinical problems by emphasizing basic principles and citing new knowledge. Their subject matter deals directly with anesthesia and its complications, and with allied topics such as resuscitation, therapy of chronic pain, management of respiratory failure, hypotension and the like.

The Society invites medical staff and county medical society officers involved in program planning to avail themselves of the services of this new Speakers' Bureau. Requests should be directed to either of the Bureau's co-chairmen, Joseph J. Buckley, M.D., Department of Anesthesiology, University of Minnesota Medical School, or J. T. Martin, M.D., Section of Anesthesiology, Mayo Clinic, Rochester.

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Classified Advertisements

Classified advertising rates are twenty (20) cents a word; minimum monthly charge $5.00; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

WANTED: General surgeon, G.P. with G.P. residency or internist to join two very busy general practitioners in new, fully equipped office in Chaska, Minnesota, 25 miles from downtown Minneapolis. Accredited hospital. Salary open. Prefer military service completed. Call collect—612-448-2050 Chaska, Minnesota, Drs. Heinzerling and Pistulka.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

WANTED: Physician wanted to join three-man group in fast-growing area just thirty minutes south of the Twin Cities. Will practice in a new clinic, new hospital and new nursing home. Salary and terms open. Contact M. H. Hunter, M.D., River's Edge Medical Clinic, Farmington, Minnesota. Telephone (612) 463-7181.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

WANTED: YOUNG PHYSICIAN for association leading to partnership with four well-established General Practitioners in fast-growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Contact: A. Eugene Muller, M.D., North St. Paul Medical Center, 2579 East 7th Avenue, North St. Paul, Minnesota 55109.

GENERAL SURGEON, Certified, part or full-time association in multi-specialty clinic. Alfred F. Anderegg, M.D., 645-5851, 2500 Como Ave., St. Paul, Minnesota.

WANTED: GP to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

DIRECTOR OF MEDICAL EDUCATION, full time —Methodist Hospital, St. Louis Park, Minnesota 55426. Contact Mr. Earl Dresser, Administrator or Dr. W. John Dawson, acting director of medical education.

WANTED: G.P. or Internist willing to do some G.P. Twin-towns totalling 12,000 western Minnesota Group now two G.P.'s and one FRCS surgeon. Modern clinic building with eight assistants, X-ray and minor laboratory, 125 bed accredited hospital. Rotating calls one night a week and every fifth week-end. Hunting, fishing, golfing available. Initial salary $1500.00 per month. Oportunity for partnership in one year. Apply to Louis T. O'Brien, M.D., Breckenridge, Minnesota.

SKIING, HUNTING, FISHING and practice of Internal Medicine offered to board qualified or certified internist by 21 man specialty clinic in northern Minnesota. Presently adding new modern facilities to keep up with rapidly expanding economy. Salary first year, shareholder status second year. Reply Russell Anderson, M.D., East Range Clinics, Ltd., Virginia 55792 or call collect, Area Code 218, 741-6244.

SEVENTEEN-MAN Wisconsin group located in college community of 40,000 with excellent hospital facilities is seeking additional associates in the following areas: (1) Internal Medicine, (2) Urology, (3) General Surgery and (4) General Practice. For further information please contact D. R. Griffith, M.D., Midelfart Clinic, Eau Claire, Wisconsin 54701.

GENERAL SURGEON interested in some general practice to associate with a 2-man partnership in a rich agricultural community in southern Minnesota. Modern hospital and new clinic building. Hunting, 9-hole golf course, swimming pool. Salary open and full partnership as soon as desired. Write: Minnesota Medicine—405, 375 Jackson, St. Paul 55101.

WANTED: General practitioner, to join two G.P.'s well established in north central Minnesota community, 2200 pop., 65 miles from Twin Cities. Excellent office space with lab and X-ray, just opened new hospital, all facilities. Assistantship or partnership. Considerable surgery and obstetrics. Hunting, fishing, golf club. Great opening for interested G.P. WRITE MINNESOTA MEDICINE—381; 375 Jackson, St. Paul, 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with early partnership. Write: MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

PRACTICE FOR SALE: Well established general practice in South Minneapolis serving an excellent community, within easy reach of the finest hospitals in the State. Very reasonable, low overhead. Splendid opportunity for solo or partnership practice. Write: MINNESOTA MEDICINE-397, 375 Jackson St., St. Paul 55101.

Law and Medicine

The Surgical Team

Legal Liability of the Individual Members

THE SURGICAL TEAM concept has become basic to the operative treatment of patients. The team is the outgrowth of the complexities of modern science, which are overwhelming and defy the understanding and the mental capacity of any one person.

The burgeoning masses of medical knowledge have taxed the ability of nearly everyone to cope with the problems presented by these changes. Scientific information accumulates more rapidly than it can be classified or applied, and the rapid technologic advances often make new pieces of equipment and technics obsolete before they can be properly evaluated. The medical profession has met the problem first by creating specialties of medicine. Thus, a young physician, a graduate of a general course in medicine, has the opportunity during residency training to concentrate his studies on a specific aspect of medicine and thereby acquire a higher degree of expertise. It becomes obvious, though, that the specialist physician, highly trained and skilled, is subject to self-imposed specialty restrictions that limit his sphere of practice. He is dependent upon other specialist physicians. But it is becoming ever more obvious that in the large medical centers of today one finds not only the major divisions (specialties) of medicine and surgery, but also many subdivisions and subspecialties in which members of the staff limit their professional activities to highly restricted aspects, as for example coronary angiography. The major specialties of yesterday have become so diversified within their own complexes that division into subspecialties has necessarily followed.

With the advent of highly sophisticated surgical procedures, it soon was recognized that during the surgical procedure the patient is well cared for by numerous persons whose vigilance and care encompass his basic physiologic requirements. Now, with the complex surgical procedures of today, the aftercare of the patient is perhaps as vitally important as the operation itself. With his expert knowledge of cardiopulmonary physiology and his skill in ventilatory technics, the anesthesiologist has had to extend his services to the postoperative period, in an effort to give the patient the most complete care possible. In the last several decades, most hospitals have created special sections where immediately postoperative care is available: the Postoperative Recovery Room, the Surgical Intensive Care Unit, the Constant Care Unit.

Serving in those units are highly trained nurses who specialize in the critical care of the immediately postoperative patients and other acutely ill patients. The concentration of the seriously or critically ill patients in specific sections within the hospital makes it possible to render the best quality of treatment with the greatest economy of professional personnel—particularly registered nurses. These special units may lower the costs of management, but the cost per patient per day in the units is increased.

Thus has medical progress brought many benefits to the surgeon and to the patient. This progress has also brought many complexities. Each specialist, in a team spirit, offers to the patient the advantage of particular skills. Each physician attending the patient participates individually, but also in the spirit of team effort. Though each physician possesses certain ethical and legal prerogatives, each must act in concert with the other consultants, thus implementing the concept of the *surgical team*.

Credit to be given:
Abstracted from the first chapter of the book: ***Law and the Physician***, (in Press) with the express consent of the copyrightholder, Williams & Wilkins Co., Baltimore, Maryland.

Nurses

The nurse's role is undergoing scrutiny by administrative officials concerned with the legal liability incurred by the nurse in the modern practice of nursing. In many respects the nurse's role is changing. Formerly the nurse was not expected to exercise judgment in the treatment of the patient, but was to carry out orders of the physician; she was not expected to originate and prescribe treatments or to make diagnoses. Such activities required the exercise of judgment. However, in the modern concept of the surgical team, the nurse is being given an increasingly responsible role in the care and treatment of the patient. An increasing number of men are becoming qualified as nurses, and male nurses supplement the staffs of many hospitals. Today physicians demand that nurses be highly trained technically and demand that they perform functions that were formerly considered far outside the nurse's prerogative. As an illustration, in the modern intensive care unit it is common for a nurse, trained in acute medicine, to institute electroshock therapy for cardioversion on a patient whose electrocardiograph monitor demonstrates ventricular fibrillation. A decade ago it would have been folly to suppose that a nurse would be defibrillating a patient's heart. Today many physicians are inexperienced in the technic, and they rely on the trained nurse to administer the new procedure of cardioversion by electroshock. It is safely practiced only under ideal situations such as exist in the intensive care units. Since the benefits of electroshock therapy depend upon early diagnosis and institution of treatment, the nurse is frequently the only trained person immediately available. When she recognizes ventricular fibrillation, she and her associates immediately institute resuscitative measures. Upon the nurse rests the life of the patient. Time is not available to await the arrival of a house physician. Thus with the acute shortage of physicians, more and more medical duties are being delegated to those who are not physicians. Many duties involve diagnosis and treatment; admittedly some even include the exercise of medical judgment. While this is thought to be legally, and by some ethically, incorrect, nonetheless it is an established practice in many modern institutions. Far from being restricted, such activities and others by nurses are being established as part of the duties of a nurse trained in acute medicine. This expansion of performance does most emphatically not entitle nurses to practice medicine, however. The above practices have been accepted generally by the profession and therefore, at least in my opinion, will be adopted by the law. The nurse is still following instructions established by the staff. Being an employee of the hospital, and carrying out routine duties not in the presence of the attending physician, the nurse is formally responsible for her acts of negligence, and the hospital is vicariously liable as her employer.

The Referring Physician

In many medical circles there is much discussion relative to the necessity of referring patients to medical centers and to the care of specialists. It is a legal axiom that consultation with another physician, particularly a specialist, is one of the great advantages if a malpractice action should result from the physician's treatment of the patient. In legal circles there has been increasing discussion relative to the degree of skill and care that must be exercised by the physician in various localities. There is no doubt that the physicians' standards differ, that is, the degree of skill of the expert must certainly, in most instances, differ from that of the general practitioner. The specialist represents himself to the public as being expert in a specific field. Therefore, according to the law, he is expected to exercise a higher degree of skill than those not expert in that field.

A physician is held to that standard of practice which is adhered to by other physicians in the same or similar community. Evidently the rule was promulgated upon the basis that all communities do not have equal facilities or physicians of equal training. For instance, a rural practitioner is certainly not expected to be as highly trained as the specialist in the large medical center. It would be grossly unfair to require the general practitioner in a rural community to have the latest diagnostic equipment, to have the facilities of the large medical centers, to have the opportunities for learning the latest developments in the field of medicine, or to have the experience of a phy-

sician who specializes within an exceedingly narrow field. Therefore the standards of practice do vary. However, the standard of practice of specialists probably does not vary as to the degree of skill. It is conceded that the degree of care required of a specialist is the same as that which is demanded of a general practitioner. "Care," in the law, is equated with and defined by the word "diligence." The law requires all physicians to be equally diligent in the care of their patients. It is the degree of skill that varies. Between specialists the degree of skill does not vary from community to community according to many of the recent decisions of the courts. Though the degree of skill of a general practitioner in a rural community is not expected to be equated with that of the medical center specialist, both types of physician must exercise the same degree of diligence.

In summary, all physicians—whether specialists or generalists—are expected to exercise the same degree of diligence in the care of their patients. The degree of skill exercised, though, depends entirely upon whether or not the physician considers himself a specialist. In either case, whether he is a generalist or a specialist, the physician is expected to exercise reasonable skill according to his role.

In the case of the generalist, the local standards are usually invoked. That is, the general practitioner is expected to exercise that degree of skill and care equivalent to that which is exercised by physicians operating under like circumstances and in the same or similar community.

On the other hand, when a physician considers himself a specialist, it is generally conceded that he is a diplomate of the American Board of his specialty. To be thus certified, the physician must have met all of the strict national requirements. In many recent decisions, the courts have taken cognizance of the fact that a physician is an expert by virtue of the fact that he is a diplomate of the American Board of his specialty. It is routine for counsel, when placing a physician upon the stand, to qualify him before the court and jury by asking direct questions as to his training and certification. Invariably, a surgeon, for instance, is asked if he is a member not only of his local, state, and national medical societies, but also if he has been certified by the American Board of Surgery, and whether or not he is a Fellow of the American College of Surgeons. Thus, both by procedural practice and by court decision, the standards of practice of the physician are gradually changing from those of yesteryear. The standards of community practice at least in regard to specialists are gradually being changed from those affected by local influence to those representing national trends.

Group Practice

The concept of the surgical team can be likened to the association of physicians who cooperate in a clinic type of practice or group practice. There was a time when the physician set up practice merely by hanging up his "shingle." Many times his office was in his home and his equipment consisted of a few diagnostic instruments such as a stethoscope and a blood pressure cuff, and a few pills and elixirs, but few specific agents. His accounting system was very simple. Not being versed in business practices, he did not keep financial records. Today the modern medical office requires the outlay of rather large sums of money for sophisticated medical equipment, both diagnostic and therapeutic. Equipment purchased today may well be rendered obsolete with the advances in medical science tomorrow. Modern business systems maintain records of the medical practice and render financial statements.

Surgical Consultation

Relatively few patients consult a surgeon directly. In most instances, the surgeon is merely a consultant to the internist, the generalist, or the family physician.

The system of referring patients to consultants who are specialized in individual fields of medicine is well established and cannot possibly be used as evidence against the referring physician. In fact, quite the opposite is usually held by courts. If this were not so, then any physician would be considered to offer prima facie evidence of his own incompetency when he recommended that a patient consult another specialist or be transferred to a medical cen-

ter. If such were the general rule of law and principle of ethics, then there would be no referrals to physicians more expert in the treatment of a given condition and thus the patient would be denied such care. The question often arises as to the liability of this referring physician and to that of the consultant. It is a general principle of law that when the referring physician relinquishes direction and control of the treatment of the patient to another physician, he is no longer responsible for the patient's welfare or for the performance of any negligent acts of the specialist. As one court has stated:

> "* * * A doctor cannot practice his profession by proxy, so, if he sends another physician to treat a patient or perform an operation and the substitute is accepted by the patient, the doctor is not liable for the independent acts of the substitute; but where a physician retains complete control and renounces no part of his functions as sole physician, but delegates to another the manual administration of the prescribed treatment, the relation of principal and agent exists, whether the person administering the treatment be a layman, a physician, or a nurse."

However, if the referring physician calls in a consultant and shares responsibility for the case, the question of liability becomes rather complicated.

In the surgical team concept and according to the regulations of many hospitals, the patient must be admitted to a primary service. In some institutions patients are admitted to joint services: that is, there are two primary treating physicians: the surgeon and the internist. Perhaps in these institutions both physicians would be considered to be treating physicians and thus primarily responsible for their own spheres of influence. There are few court decisions involving members of the surgical team; therefore some legal details remain unclear. While there seems to be little difference in the role of consultants vis-a-vis the role of the individual members of the surgical team, perhaps there may be some important technical differences.

Today, although the surgeon may represent the primary service, his role sometimes is rather minor in comparison to the roles of others on the surgical team. In this situation plaintiff lawyers name all the members of the surgical team: nurses, physicians, orderlies, and others, the hospital, and a pharmaceutical or equipment manufacturer, in any suit. Each defendant disclaims responsibility and thus enables the plaintiff to "make his case" on his opposition. The surgeon too dislikes individual legal liability and is most eager to share responsibility with all members of the surgical team.

Physician-Patient Relationship

It becomes evident that in the modern concept of the surgical team, each member must establish rapport with the patient. Without question the surgeon must confer with the patient or the patient's family concerning the intended surgical procedure. The fact that the surgeon has a crowded professional schedule does not release him of legal liability to communicate with the patient or those responsible for him. Lack of rapport is probably the most important single cause of malpractice action against a physician. Indeed, it was lack of physician-patient rapport that led to the development of what has been termed "informed consent."

The patient who is unaware of the full implications of the surgical procedure contemplated might well have not given an adequate legal consent for the procedure. It is axiomatic in the law that all patients who enter a hospital under the doctrine of the assumption of risk, at least impliedly grant permission or consent or authorization for treatment. However, in the modern hospital, the possibility of an unauthorized treatment being instituted assumes great importance. The present-day surgical team might consist of more than a surgeon and an anesthesiologist. Many persons may be involved. Each by his individual role—unless each clearly explains his function and activities to the patient—may commit a surgical or medical assault and battery upon the patient.

Any association of physicians may lead to legal entanglements. Irrespective of the fact whether the agreement of association is based on accounting or bookkeeping and office-sharing or equipment-sharing, there may well be in law an *agency by estoppel* established between these several members of such an agreement. The fact that no formal partnership papers have been drawn does not preclude the

possibility of the existence of such an agency between a physician and the surgical team. In formal partnerships each physician is an agent of the partnership and the actions of any one partner may well bind the others. Therefore it is incumbent upon each physician contemplating such an association with another physician to consult an attorney for his advice and guidance. Indeed, if any agreement is established it is strongly recommended that such a contract or written instrument be reviewed periodically in order to determine whether it does in fact express the intent and present objectives of those in the association.

One serious fault of some physicians is their failure to know their limitations. It is recognized that a physician in an isolated community will be faced with serious surgical emergencies that he is not trained to treat. His rendering of emergency aid to a patient does not subject the treating physician to other more stringent rules than the exercise of reasonable care and skill. However, this same physician may not with impunity undertake to perform complicated elective procedures under the supposition that he may assume the legal protective cloak he may enjoy in emergency situations. In regard to such elective operations, he may be held to the standard of care and skill of the surgeon who is expert in the field.

In a hospital where professional qualifications are not investigated thoroughly, or where the rules of the staff are not enforced strictly, some physicians will perform operative procedures in which they have little or no training. It must be understood that the law will require them to have reasonable skill. Should a surgeon wish to carry out a new procedure, or one with which he has little experience, then the patient should be apprised of this fact.

The interrelationships of the members of the surgical team become increasingly difficult to differentiate and may lead to many possible legal complexities. A physician, as a member of the team, becomes professionally dependent on others on the team, and his legal responsibility thereby becomes more and more involved with that of his associates.

Carl E. Wasmuth, M.D., J. D.*
Cleveland, Ohio

*Head, Department of Anesthesiology, The Cleveland Clinic Foundation; Adjunct Professor of Law and Director of Division of Legal Medicine, Cleveland-Marshall College of Law, Cleveland, Ohio.

Diagnostic Acumen

The physician should be of tender disposition, of wise and gentle nature, and more especially an acute observer, capable of benefiting everyone by accurate diagnosis, that is to say, by rapid deduction of the unknown from the known. And no physician can be of tender disposition if he fails to recognize the nobility of man; nor of philosophical nature unless he be acquainted with Logic; nor an acute observer unless he be strengthened by God's guidance; and he who is not an accurate observer will not arrive at a correct understanding of the cause of my ailment.*

*Edward Browne: Arabian Medicine.

The true test of civilization is, not the census, nor the size of cities, nor the crops, but the kind of man that the country turns out.—Emerson

---

This also is a season of discovery. A lot of presidential timber is finding out it's nothing but kindling.—Changing Times

(Continued from page 1150)

THE WEST MEDICAL CLINIC has an opening for a General Practice Physician, on October 1, 1968. This is a five man group that conducts a practice near downtown St. Paul and also, has the Airport Medical Clinic at Wold Chamberlain Field, Twin City International Airport. Both clinics have full laboratory and x-ray services with technologists covering both fields.

The Airport Medical Clinic does industrial, occupational and Aviation medicine. FAA examinations are conducted at both clinics.

The clinic located near downtown St. Paul has a practice limited principally to internal medicine, pediatrics, as well as occupational and industrial medicine. There is only a limited practice of obstetrics and no surgery.

Salary is open and opportunity for partnership is available. Write: West Medical Clinic, 539 W. Seventh Street, St. Paul, Minnesota 55102. Phone: Area Code 612-227-9341.

FOR SALE: Practice—clinic—apartment bldg.—military-exempt town—will retire—14-room clinic-dental suite; four apartments. Apartments will retire costs. Two good schools and churches—good farming area. New large swimming pool—18 hole golf course playable this summer—theatre—bowling alley. 17 miles from St. Olaf Hospital, Austin. Write—P. J. Schneider, M.D., Adams, Minn. 55909.

FOR SALE: 1. Ritter Table—all purpose, with electric hydraulic lift and manual tilt, excellent condition, less than 50% of replacement. 2. Burdick Ultra Sound, perfect working order. 3. Office Scale. 4. Cole Metal Desk, double pedestal, matching swivel and arm chairs, sandalwood. 5. Trial Lens Set. 6. Disposable Sigmoidoscope Rechargeable. 7. Older X-Ray Unit, fixed table, 100 ma, stainless steel developing tanks. J. T. Adkins, M.D., 612-427-2079 (home) or 612-755-1621 (office).

ANOKA-MINNEAPOLIS excellent openings for psychiatrist—unit chief & staff physicians. 600-bed open-door hospital. Salary $16-$28,500. Apply Medical Director, Anoka State Hospital, Anoka, Minnesota 55303.

DOCTOR WANTED: General practitioner to join growing practice in aggressive Northwestern Minnesota community of 750. Trade area numbers in excess of 5000. Average age of 30 key businessmen in community is 36. Eighteen bed hospital operating and plans are currently in formation to add to acute bed numbers plus construction of a nursing wing. Direct inquiries to Joel Spilde, Administrator, Karlstad Memorial Hospital, Karlstad, Minnesota 56732. Telephone 218-436-3375.

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55102.

PRACTICE AVAILABLE: A well-established general practice of 36 years in south Minneapolis with a well equipped office. Must retire because of physical disability. If interested phone 822-0493 after 7:00 P.M. any day, or write MINNESOTA MEDICINE 411; 375 Jackson, St. Paul, Minnesota 55101.

DESIRE TO GIVE away a general surgery practice which should immediately provide a versatile surgeon with 200 majors annually and unlimited ceiling. Will provide modern office facilities in a ten-year-old clinic building and guarantee a minimum income with no strings attached. Should be board qualified and under forty-five. Excellent hospital facilities with resident anesthesiologist and pathologist. Reason:—desire to limit my practice to Urology. Write or call O. K. Behr, M.D., 407 North Broadway, Crookston, Minnesota—Area Code 218-281-3210.

WANTED BY TWO INTERNISTS—a Board Eligible or Board Certified Internist to practice in the Twin City area. Excellent opportunity and early partnership. Write: MINNESOTA MEDICINE-407, 375 Jackson, St. Paul, 55101.

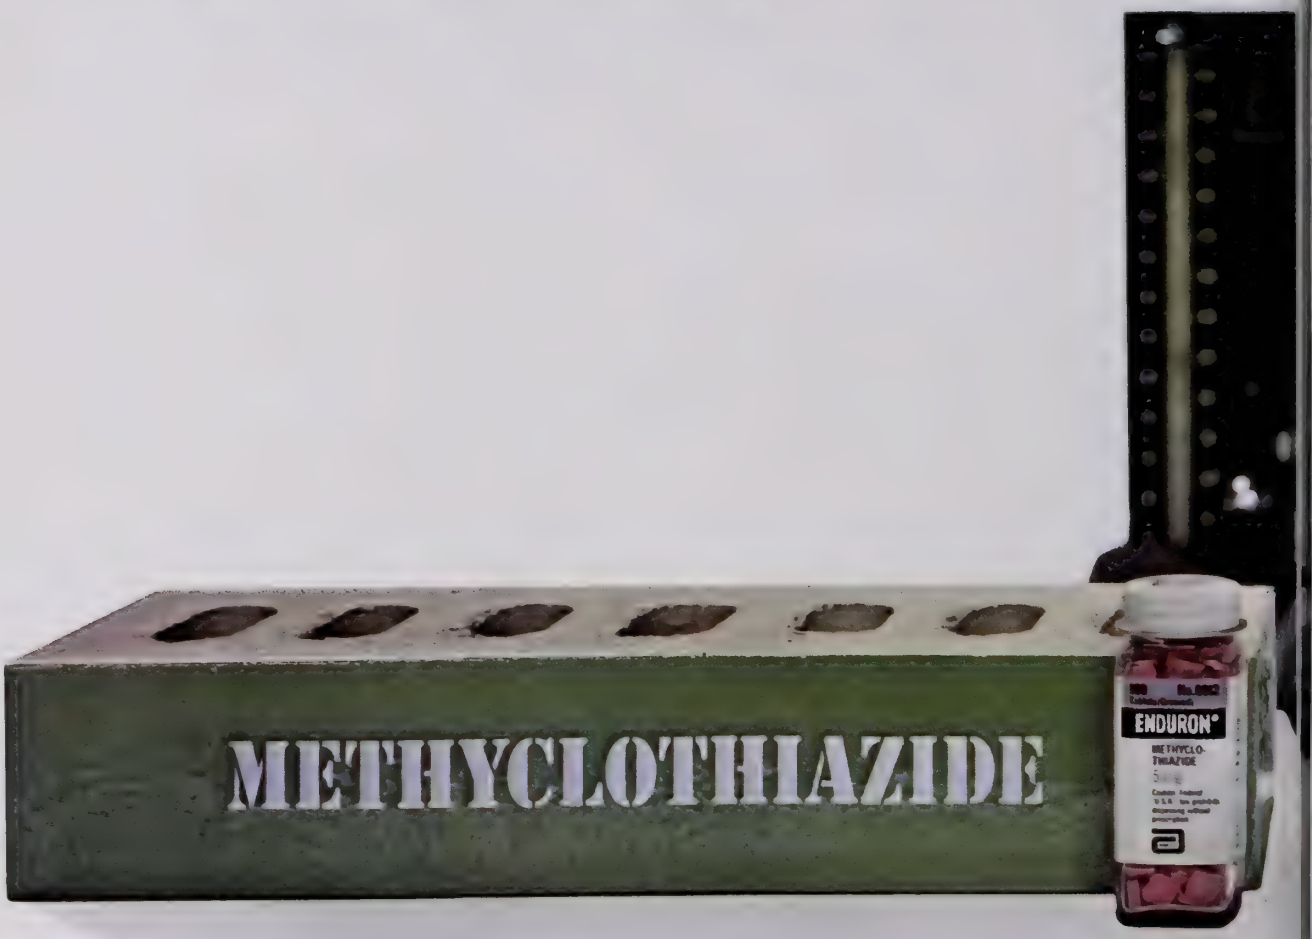
WANTED—Board Certified or eligible Internist to join two established Internists in medium sized, college community in Minnesota lake country. New clinic facilities. Salary negotiable. Write MINNESOTA MEDICINE 409, 375 Jackson, St. Paul 55101.

PHYSICIAN NEEDED IMMEDIATELY—Attractive opportunity for general practitioner in rapidly expanding all new community of Silver Bay, Minnesota, a growing world's first large scale taconite center. Area population 6,000 on beautiful Lake Superior, gateway to Northern Minnesota's infinite vacation variety land. The area's natural resources for year round sports and recreation are unexcelled—good hunting, skiing, golfing—near metropolitan area of 125,000 population. Attractive financial arrangements and liberal fringe benefits for physician to take care of medical industrial needs of Reserve Mining Company in addition to private practice. Present doctor near retirement age presents wonderful opportunity for physician to relocate or young physician wishing to establish rewarding practice; excellent monetary potential proportionate to ability and desire to work. No investment necessary. Submit resume of education and experience in confidence to John A. Smrekar, Reserve Mining Company, Silver Bay, Minnesota 55614

WANTED: General practitioner, licensed in Minnesota, for staff at State-operated Ah-gwah-ching Nursing Home, 481 beds, located in the heart of Minnesota's vacationland, on Leech Lake; forty-hour week, annual vacation, sick leave, and other state Civil Service benefits. Retirement benefits: state-paid life insurance, Blue Cross and Blue Shield coverage . . . night and weekend duty on rotation basis. House, including heat, light, telephone provided in addition to salary. Write Ah-gawh-ching Nursing Home, H. M. Williams, M.D., Superintendent, Ah-gwah-ching, Minnesota 56430.

FOR RENT: 14-room deluxe clinic in shopping center—Robbinsdale. 5 min. from Glenwood Hills and No. Memorial Hospitals—3 months rent free—will subdivide—36th Ave. No. and Noble—Noble Drug, JU 8-9449—Ben or Lou.

GENERAL PRACTITIONER WANTED: To associate with Physician-Surgeon in Owatonna, a Southern Minnesota community, 25,000 population. Clinic building 3 years old, with five large treatment rooms, lab., x-ray, central supply, two doctors' offices, pharmacy, and business offices. Located next door to 85 bed City Hospital. Good opportunity for partnership. Contact: O. W. Roberts, M.D., 920 South Cedar Street, Owatonna, Minnesota. Phone 451-4630.



Continued to page 1162

Abbott Antihypertensive Building Blocks

A simplified approach to the practical management of hypertension

Enduron: (methyclothiazide) A basic building block for mild hypertensives

Excellent day-long Na^+ output, yet easy on the K^+

Enduron provides an excellent starting therapy. Your patient's sodium excretion is greatly enhanced. Yet potassium loss is low.

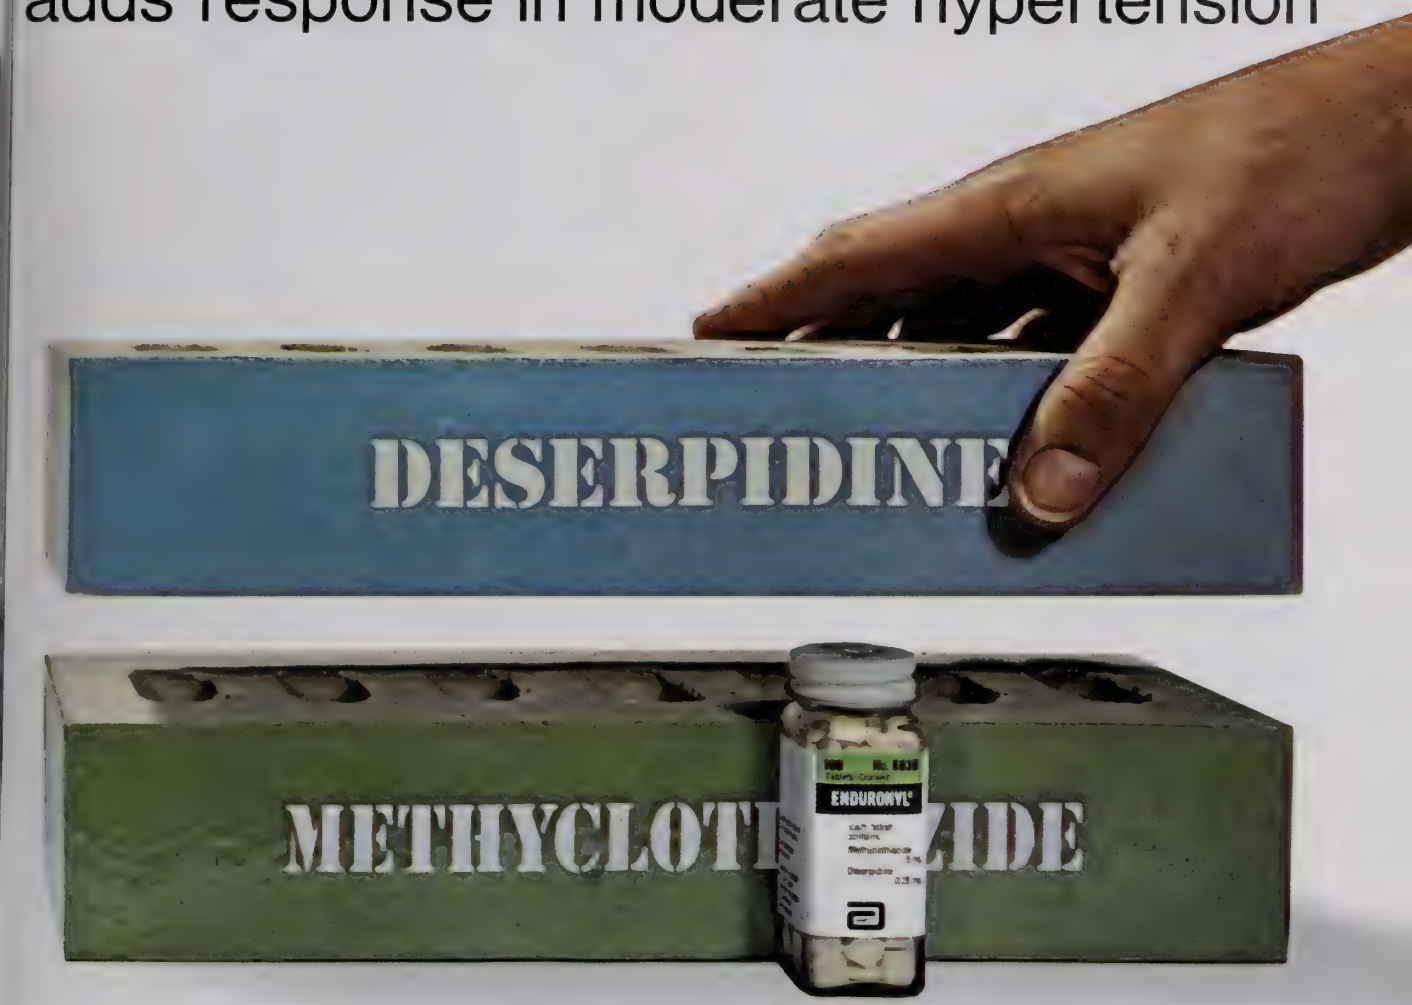
The therapeutic action is smooth, and persists for a full 24 hours. With Enduron you can prescribe convenient once-a-day dosage without skimping your patients on day-long thiazide effectiveness.

Of course, as with all thiazides, supplemental dietary potassium should also be considered.

Use Enduron as a basic therapy in patients with mild to moderate hypertension. A single 5-mg. tablet each day is ample in most cases.

Once a day, every day

ENDURON



METHYCLOTHIAZIDE

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

Enduronyl: Its deserpidine component adds response in moderate hypertension

Less frequent rauwolfia side effects than with reserpine

When you wish to build further response, consider shifting to Enduronyl.

Enduronyl adds a building block of *deserpidine*. This is a purified rauwolfia alkaloid available only from Abbott. It adds good antihypertensive and tranquilizing activity. Yet its incidence of untoward effects, particularly lethargy and depression, is lower than with reserpine.

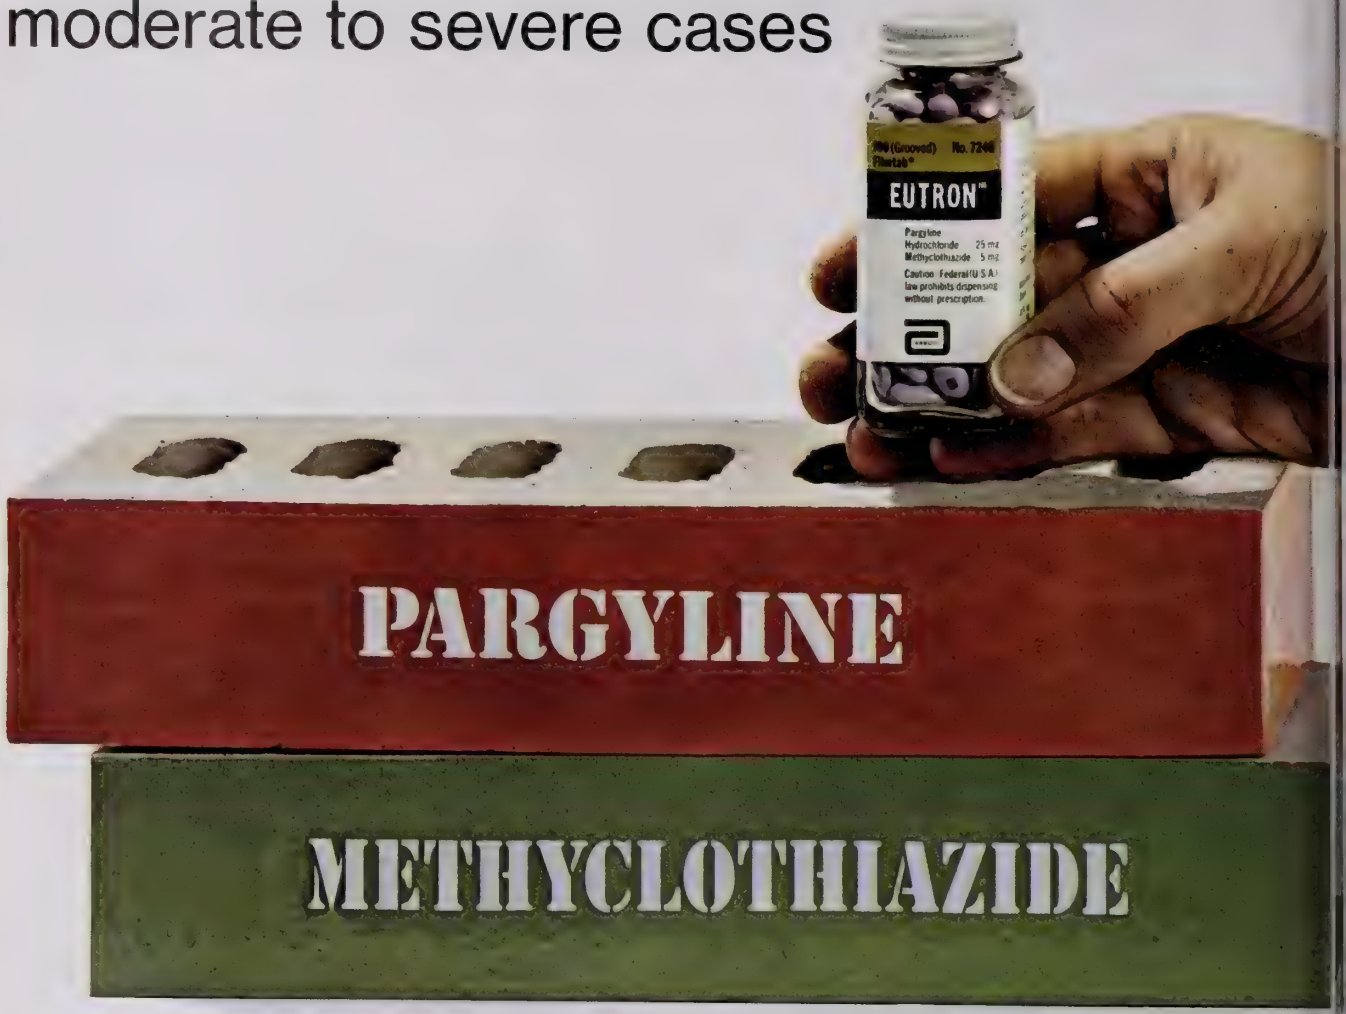
Enduronyl is available plain or Forte. The latter provides its variation where most helpful, by doubling the deserpidine.

Use Enduronyl for patients throughout the broad range of mild to moderately severe hypertension.

Once a day, every day

ENDURONYL®

METHYCLOTHIAZIDE 5 mg. with DESERPIDINE 0.25 mg. or (FORTE) 0.5 mg.



MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

Eutron: A unique combination for handling moderate to severe cases

Affords almost uniform diastolic reduction in all body positions

Eutron lowers diastolic pressures nearly equally, whether your patient is standing up or lying down.

Thus, in clinical trials, average *standing* diastolic readings were reduced from 112 pre-treatment to 90 post-treatment; *sitting* from 115 to 95; and *recumbent* from 112 to 94.

Note that following Eutron, the diastolic reductions were nearly alike in all three body positions.

Use Eutron for managing your moderate to severe cases. Its building blocks enhance each other; hence lesser doses often suffice.

Once a day, every day

EUTRON™

PARGYLINE HYDROCHLORIDE 25 mg.
with METHYCLOTHIAZIDE 5 mg.

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

ENDURON® | ENDURONYL®

METHYCLOTHIAZIDE

Each tablet contains
Methyclothiazide 5 mg. with
Deserpidine 0.25 mg. or 0.5 mg.

Indications: Edema and mild to moderate hypertension (Enduron), and mild to moderately severe hypertension (Enduronyl). More potent agents, if added, can be given at reduced dosage.

Contraindications: Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease or impending hepatic coma (hepatic coma due to hypokalemia has been reported in patients on thiazides). Do not use Enduronyl in severe mental depression, suicidal tendencies, active peptic ulcer, or ulcerative colitis.

Warnings: Consider possible sensitivity where there is history of allergy or asthma. If added potassium is indicated, dietary supplementation is recommended. Reserve enteric-coated potassium tablets for cautious use only when necessary, as they may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation often requiring surgery; discontinue them immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occurs. Neither Enduron nor Enduronyl contains added potassium.

Precautions: Use thiazides cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery, thiazides may reduce response to vasopressors, and increase response to tubocurarine. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia) in all patients. In hypokalemia (especially in digitalized patients) give supplemental potassium. In hypochloremic alkalosis, give supplemental chloride.

Use rauwolfias with caution in patients with history of peptic ulcer. Rauwolfias with anesthetics may produce hypotension and bradycardia. Discontinue Enduronyl two weeks before elective surgery. Consider vagal blocking agents during emergency surgery. In epilepsy, adjust anticonvulsant dosage. In electroshock, shorten stimulus strength and duration. In occasional patients with depressive tendencies, rauwolfias may precipitate severe mental depression that usually disappears when drug is stopped.

Adverse Reactions: Thiazide reaction include blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, serum uric acid or blood sugar; anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, symtomatic gout, and pancreatitis. Cutaneous vasculitis in the elderly has been reported with other thiazides. Adverse effects with deserpidine are qualitatively similar to those with reserpine, but their incidence is lower. These include nasal stuffiness, abdominal cramps or diarrhea, nausea, headache, weight gain, reduced libido and potency, peptic ulcer aggravation, epistaxis, skin eruption, asthma in susceptible patients, electrolyte imbalance, excessive salivation, and a reversible Parkinson's syndrome. Excessive drowsiness, fatigue, weakness, and nightmares may signal mental depression. Thrombocytopenia, purpura, and a symptom manifested by dull sensorium, deafness, uveitis, glaucoma, and optic atrophy are rare allergic reactions to other rauwolfias. Hypotension from antihypertensive agents may precipitate angina attacks in susceptible individuals. Usually adverse reactions disappear when drug is withdrawn.

EUTRON™

Each tablet contains
Pargyline Hydrochloride 25 mg.
with Methyclothiazide 5 mg.

Indications—Moderate to severe hypertension.

Contraindications—Pheochromocytoma, paranoid schizophrenia, hyperthyroidism and advanced renal failure. Not recommended in malignant hypertension, children under 12, pregnant patients.

Do not use with: centrally or peripherally acting sympathomimetic drugs; foods high in tyramine (e.g., aged and natural cheeses); parenteral reserpine or guanethidine; imipramine, amitriptyline, desipramine, nortriptyline or their analogues; other monoamine oxidase inhibitors; methyldopa or dopamine; separate Eutron and these agents by two weeks.

Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease; impending hepatic coma from thiazide-induced hypokalemia.

Warnings—Patients: 1. No other drugs (particularly "cold preparations" and antihistamines), cheese or alcohol without physician's consent. 2. Promptly report orthostatic symptoms, severe headache, other unusual symptoms. 3. Angina pectoris or coronary artery disease patients must not increase physical activity with improved anginal symptoms or well-being.

Physicians: 1. Use antihistamines, hypnotics, sedatives, tranquilizers and narcotics (meperidine contraindicated) cautiously in reduced doses. 2. Stop Eutron two or more weeks before elective surgery; in emergency surgery reduce premedication (narcotics, sedatives, analgesics, etc.) to 1/4 to 1/5; carefully adjust anesthetic dosage to patient response. 3. Use cautiously in advanced renal failure. 4. Pargyline may induce hypoglycemia. 5. Consider possible sensitivity reactions when a history of allergy or asthma is present. 6. If potassium is indicated, dietary supplement is recommended; enteric-coated potassium tablets may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation frequently requiring surgery; discontinue medication immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occurs; Eutron does not contain added potassium. 7. Possible systemic lupus erythematosus has been reported for thiazides.

Precautions—Pargyline: Use cautiously at reduced dosage: caffeine, alcohol, antihistamines, barbiturates, chloral hydrate, other hypnotics, sedatives, tranquilizers, narcotics. Periodically do urinalyses, blood counts, liver function tests, etc. Use with caution in liver disease. Watch for orthostatic hypotension, especially in impaired circulation (e.g., angina pectoris, coronary artery disease, cerebral arteriosclerosis); also, augmented hypotension in concomitant febrile illnesses. Reduce or discontinue if hypotension is severe. In impaired renal function watch for cumulative drug effects, elevated BUN and other evidence of progressive renal failure; withdraw drug if these persist. In surgery increased central depressant response (hypotension and increased sedative effect) can be controlled by (1) discontinuing at least two weeks prior; (2) in emergency surgery lowering dose of premedication; (3) when necessary, administering a vasopressor. Do not use in hyperactive and hyperexcitable patients. Pargyline may unmask severe psychotic symptoms where emotional problems pre-exist. Use cautiously in Parkinsonism, especially with antiparkinsonian agents. In prolonged therapy, examine for change in color perception, visual fields, fundi and visual acuity. Also, prolonged therapy has made certain patients refractory to nerve blocking effects of local anesthetics.

Methyclothiazide: Use cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery thiazide may reduce vasopressor response and increase tubocurarine response. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia). Give supplemental chloride if hypochloremic alkalosis occurs and supplemental potassium if hypokalemia occurs (especially in digitalized patients). Thiazides may decrease serum P.B.I. without signs of thyroid disturbance.

Adverse Reactions — Pargyline: Orthostatic hypotension and associated symptoms, mild constipation, fluid retention, edema, dry mouth, sweating, increased appetite, arthralgia, nausea, vomiting, headache, insomnia, difficult in micturition, nightmares, impotence, delayed ejaculation, rash, purpura, weight gain, hyperexcitability, increased neuromuscular activity and other extrapyramidal symptoms. Drug fever is extremely rare. Reduction in blood sugar and hypoglycemic effects are possible. Congestive heart failure has been reported in a few patients with reduced cardiac reserve.

Methyclothiazide: Blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, blood sugar or serum uric acid (gout may be induced); anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice and pancreatitis. Cutaneous vasculitis in elderly patients has been reported with other thiazides.

If side effects are severe or persist, reduce dosage or withdraw drug. 804438R

GENERAL PRACTITIONER: Serve as Medical Director of 50-bed Minnesota State Prison Hospital; staff of registered nurses, surgical nurse, laboratory technician, dentist, and consultants with various specialties; surgical residents provided by University of Minnesota Hospitals; salary $20,800 to $27,800 based on experience and qualifications; benefits include hospitalization and life insurance, vacation and sick leave accruals, liberal retirement program; located in Stillwater, Minnesota, in the recreational St. Croix River Valley; 30 minutes from Minneapolis-St. Paul by freeway. Contact Personnel Department, Box 55, Stillwater, Minnesota 55882.

GENERALIST as member of Medical Staff of progressive State Hospital in Michigan's Vacationland. Hospital has 3-year accreditation. JCAH and 3-year residency accreditation by A.P.A. Salary $17,867.20 to $21,777.60. Excellent fringe benefits. Civil Service security when qualified. Apply L. B. Young, M.D. Director of Medical Services, Traverse City State Hospital, Traverse City, Michigan 49684.

ST. PAUL: Spacious suite in new split-level building, partitioned for medical offices. Other level occupied by dentist. Excellent location adjacent to large shopping center. 1504 White Bear Avenue, 774-7144.

FOR SALE: 2 exam room units. Also new Cambridge EKG, Hematocrit, and various other equipment. Call Faribault 507—334-7739 or write Dr. A. D. Mattson, 808 Home Place, Faribault. Minn. 55021.

Southern Minnesota Medical Association

The annual convention for the Southern Minnesota Medical Association will be held Friday, September 20, 1968 at the Owatonna Country Club in Owatonna, Minnesota. The program will be published in the September issue of MINNESOTA MEDICINE. Contact: Dr. Robert Conley, Mankato Clinic, Mankato, Minnesota.

Minnesota Medicine at a Glance

Fat Embolism—*Evarts* Page 1035.

Fortunately, fat embolism is not sufficiently frequent to keep it constantly in mind, though it should be one of the concerns of a physician who is seeing patients that have been injured. Ninety percent of the patients with fat embolism demonstrate their symptoms within a period of 48 hours after injury.

The signs, symptoms and treatment of this sequel to trauma are very lucidly demonstrated in Evarts' manuscript.

Myocardial Revascularization Surgery—*Effler* Page 1039.

At the Cleveland Clinic more than 1500 internal mammary artery implant procedures have been performed in the past six years and, as experience has been gained, the procedures used for restoring circulation to the deficiently functioning myocardium have been found to have increasing value. Effler and associates use a combination of the Vineberg and the Sewell procedure. Proof of its value has been established by postoperative internal mammary arteriography, with the best results obtained on those patients who have increasing angina pectoris in which the coronary arteriogram demonstrates almost complete obstruction of the major coronary artery.

Bacterial Infection Emergencies—*McHenry & Van Ommen* Page 1043.

These authors discuss clinical emergencies due to bacterial infection and point out that shock may be associated with bacteremia due to gram-negative bacilli. Other factors causing similar emergent problems are acute bacterial meningitis, fulminating meningococcemia, acute bacterial endocarditis and staphylococcal enterocolitis. The various factors causing these emergent conditions and the management are discussed.

The Cadaver Kidney as a Donor—*Straffon et al.* Page 1049.

One hundred seventeen renal transplants were from cadaver donors. In this group the one-year survival rate was 48%, and two patients have entered their fifth year with a functioning renal allograft from a cadaver donor. These authors consider that renal transplantion along with intermittent hemodialysis must be considered as therapy for the patient with terminal renal failure.

Essential Hypertension—*Vidt & Gifford* Page 1055.

Special attention has been paid to the diastolic blood pressure in hypertension. The authors have outlined therapeutic regimens for complicated and uncomplicated hypertension. They point out that as long as the diastolic blood pressure does not exceed 100 milligrams and the systolic pressure does not exceed 220 milligrams mercury, treatment is probably not necessary unless there is heart failure.

Colonic and Rectal Polyps—*Hawk et al.* Page 1063.

This manuscript deals principally with the symptoms, histopathology and recognition of polyps that are encountered in young individuals. In those polyps under discussion there is very little chance of lethal malignancy occurring; therefore the treatment can in large part be limited to local management. Electrosurgical excision, these authors point out, minimizes the possibility of implantation if the lesion should prove to be malignant.

LIBRARY OF THE
COLLEGE OF PHYSICIANS
OF PHILADELPHIA
SEP 23 1968

McKinley Unmasked

Thomas J. Kinsella, M.D.

SEPTEMBER, 1968

An antibiotic should work well in either acid or alkaline urine.

It isn't always necessary to adjust urinary pH in treating G.U. infections.

Not when the causative organism is a strain sensitive to DECLOMYCIN® Demethylchlortetracycline, as is often the case.

DECLOMYCIN remains stable and active in either acid or alkaline urine. So there's no need to acidify the urine to keep the antibiotic at work.

Why match the urine to the antibiotic...when you can match the antibiotic to the urine...by prescribing DECLOMYCIN. A b.i.d. dosage makes therapy convenient for your patient.

Effectiveness: DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines in infections caused by organisms sensitive to the tetracyclines.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system – anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin – maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney – rise in BUN, apparently dose-related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions–urticaria, angioneurotic edema, anaphylaxis. Teeth – dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Demethylchlortetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

Capsules: 150 mg; Tablets: film coated – 300 mg, 150 mg and 75 mg of demethylchlortetracycline HCl.

You can be there with NCME TV!

The first nationwide medical television service, NCME—The Network for Continuing Medical Education—brings you visually the important achievements of leading medical authorities. By means of closed-circuit television, this independent network provides your hospital or medical school with a complete videotape service that helps shorten the gap between new medical knowledge and its availability for clinical or teaching purposes.

NCME
The Network for Continuing Medical Education

NCME TV Offers These Practical Benefits:

☐ Every two weeks a new 60-minute videotape dealing with three separate medical subjects is sent to participating institutions.

☐ Content and format of NCME telecasts fulfill criteria for postgraduate medical education, permitting American Academy of General Practice course credits under specified conditions.

☐ To help your institution make effective use of closed-circuit television, NCME offers a wide range of services and utilization aids, including: Technical consultation in setting up a closed-circuit system; advance program information on the contents of each telecast; display units to help publicize programs; expense-paid seminars to improve utilization of medical television.

☐ NCME programs are brief and may be shown as often as desired; you can view the telecasts at times that are most convenient, without disrupting your normal schedule.

☐ Frequently NCME makes available published papers related to subjects presented on closed-circuit television.

A recent NCME hospital telecast presented Philip N. Sawyer, M.D., Professor of Surgery and Head of the Vascular Surgical Service at Downstate Medical Center, Brooklyn, N.Y., in a demonstration and evaluation of "Gas Endarterectomy."

In this program, Dr. Sawyer performs the operation on a patient with gross occlusion of the right iliac, femoral and popliteal arteries.

In Dr. Sawyer's view, gas endarterectomy has several advantages over mechanical methods: the operation can be completed faster, causes less damage to the arteries and offers a more successful outcome.

NCME is an independent network supported by Roche Laboratories to increase the use of closed-circuit TV for medical education under direct hospital and school control.

If your hospital or school does not participate in the biweekly NCME program, information on the cost-free service may be obtained by writing to NCME, 342 Madison Avenue New York, N.Y. 10017

GENERAL INFORMATION

Authors

Send manuscripts, subscriptions and communications for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101. Telephone 222-6366.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Some U.R.I. patients are more miserable than others.

That's why we make Novahistine® tablets in two different formulations.

And let you control the dosage.

Each Novahistine LP tablet contains phenylephrine hydrochloride, 25 mg.; and chlorpheniramine maleate, 4 mg.
Each Novahistine Singlet tablet contains phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; and acetaminophen, 500 mg.

With Novahistine LP tablets and Novahistine Singlet™ tablets you have the range and flexibility of decongestant dosage that lets you prescribe for the needs of the individual patient.

Novahistine LP tablets are most useful for relief of nasal congestion in patients without pain or fever. Novahistine Singlet tablets, which provide analgesic-antipyretic effect, as well as decongestant action, are indicated for upper respiratory infections accompanied by pain, aches and fever.

Whether you prescribe Novahistine LP or Novahistine Singlet, a total daily dose of 3 or 4 tablets will usually provide effective, continuous relief.

Use cautiously in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

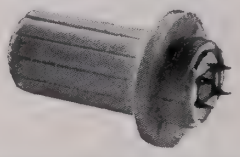
BETTMAN ARCHIVE

Just one tablet at bedtime • Prevents painful night leg cramps • Permits restful sleep

How many of your patients stamp their feet at night and lose sleep because of painful leg cramps? Unless prompted, they usually fail to report this distressing condition and suffer needlessly.

One tablet of QUINAMM at bedtime usually controls distressing night cramps and permits restful sleep with the initial dose.



Prescribing information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Side Effects/Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

President's Letter

Otolaryngologists, Let Us Face the Facts!

THERE IS A dire need for ear, nose, and throat specialists all over the country. In our own state of Minnesota, for example, such specialists are concentrated mainly in three cities: Minneapolis, St. Paul, and Rochester. In fact, 30 years ago we had more ear, nose, and throat specialists in the smaller communities than we have today.

The Board of Certification has made great efforts to improve the quality of the specialty by lengthening the training program and providing stricter control of the educational centers. This has provided a trend toward subspecialization and has encouraged congregation in large cities. Somehow, the people living in smaller towns have been forgotten.

In an effort to provide a more even distribution of the specialty, a more flexible training program is urgently needed: that is, a plan for a three-year program in general ear, nose, and throat training. This program could be made more effective by severely reducing the time spent in general surgical training during the internship. Training should be extensive enough, however, so that the graduate student is qualified for board examination. A five-year or even a six-year program should be set up for the more academic and research-oriented students and also for those who elect to enter a subspecialty.

Examination of the Comatose Patient*

MILTON ALTER, M.D., Ph.D†
Minneapolis, Minnesota

IN EVALUATING a comatose patient, the physician must have in mind a list of possible causes. The three main causes are oxygen deficiency, substrate deficiency, and enzyme disturbances.

Causes of Coma

Oxygen Deficiency

The brain's metabolism is dependent upon aerobic processes, and it has no storage capacity for oxygen. Deprivation of oxygen, even for a few moments, interferes with the ability of the brain to function and manifests clinically as impaired consciousness. The cause of the oxygen deprivation may be generalized, as encountered in an airplane whose oxygen supply is suddenly lost, in an anemic individual whose blood cannot carry enough oxygen, or in an individual with a myocardial infarction, whose brain is poorly perfused with blood. On the other hand, the oxygen deficit may be localized, as when a vessel in the brain becomes occluded or a major artery is stenotic.

Substrate Deficiency

In the brain, the major metabolite is glucose. For practical purposes the brain utilizes no other substrate. Hence, in the presence of coma, the clinician should examine the glucose level in the blood. Ideally he should examine the glucose available to the central nervous system, since there may be a discrepancy between the blood level of glucose and the amount of glucose on the central nervous system side of the blood-brain barrier. However, as this is seldom practical, a blood sugar must suffice.

Enzyme Disturbance

Enzyme disturbances occur in a number of conditions. Those which should be considered include diabetes, uremia and hepatic failure. Insulin is the enzyme which is deficient in

*Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.
†Chief, Neurology Service, Veterans Administration Hospital, and Associate Professor, Division of Neurology, University of Minnesota, Minneapolis, Minnesota.

diabetes, and renal failure probably involves impaired function of many enzymes. The specific enzymatic defects in liver failure are not known, but probably ammonia metabolism is involved in some way as ingestion of protein aggravates the mental aberrations when the liver is failing and blood ammonia levels rise.

Ionic disturbances affect enzyme function, at least in part, by interfering with pH. Accumulation of CO_2, for example, may cause a shift toward the acid level in the blood and create a condition in which some enzymes work less efficiently. Accumulation or depletion of water affects the concentration of ions and may produce levels which are detrimental to the function of certain enzymes.

Other Factors

Exogenous factors such as temperature changes and exposure to organic and inorganic toxins affect enzyme function and may impair consciousness. Deficiency or excess of cofactors, such as vitamin B_1, essential for brain metabolism, may likewise interfere with brain function.

Table 1 also lists conditions in which multiple factors are involved in accounting for coma. Trauma is an example in which oxygen may be deficient, cerebral vessels may be torn, and the functions of many enzymes may be disturbed. It should be realized that the factors mentioned in Table 1 represent only a partial list.

In many cases, the cause of the coma will be obvious: for example, trauma to the head. These cases are mainly management problems. However, the cause of the coma is sometimes obscure, and it is worthwhile to examine the experience of Plum and Posner[1] as regards the frequency of various causes of coma in cases referred to them initially as "etiology unknown" (Table 2).

Examination of the Comatose Patient

While history usually suffices to clarify the etiology of coma, the examination will indicate where the lesion is. Of course, the evaluation must be thorough, but often the patient's precarious state hardly allows a leisurely work-up. It is important, therefore, to concentrate on those aspects of the examination which are likely to be most informative as to site of the pathology. There are a number of questions which the physician must keep in mind when making his evaluation of the patient in coma.

What is the Level of Consciousness?

An *alert* patient responds fully, immediately, and appropriately to stimuli. A *lethargic* patient is drowsy, indifferent and slow and gives incomplete responses. *Obtundation* is characterized by duller indifference with wakefulness barely maintained, while a *stuporous* patient can be roused only by strong stimuli. *Moderately deep coma* is present when only rudi-

mentary reflex responses to strong stimuli occur, e.g., withdrawal, sucking, chewing, swallowing. With *deep coma* no motor responses occur even to strong stimuli. It is well to remember that agitation, confusion, disorientation, inattention, delirium and misperception (illusions and hallucinations) are signs of impending coma.

How is the Patient Breathing?

Posthyperventilation apnea consists of persistent apnea (>12 secs.) after hyperventilation. The mechanism is not clear in all its details, but depressed consciousness, usually from bilateral hemispheric disturbance, is thought to interfere with central (forebrain) control of the response to pCO_2. In posthyperventilation apnea, the respirations stop when deep breathing has lowered pCO_2 to 8-14 mm Hg. Normally, rising pCO_2 triggers breathing within 10 seconds. In abnormal subjects, apnea may persist 12 to 30 seconds or more after hyperventilation.

In Cheyne-Stokes respirations, hyperpnea alternates with apnea periodically. This breathing pattern suggests damage in deep portions of cerebral hemispheres and basal ganglia with involvement of the internal capsule. It may indicate impending herniation. It represents an abnormally increased response to pCO_2 and decreased sensitivity of the forebrain to ventilatory stimuli.

Central neurogenic hyperventilation is characterized by regular, rapid, deep respirations and usually occurs with a lesion in the tegmentum from the lower part of the midbrain down to the lower pons. It is often caused by blood irritating reticular gray matter around the Sylvian aqueduct and fourth ventricle. It produces respiratory alkalosis and is not modified by administration of O_2.

Apneustic breathing* consists of a prolonged inspiratory cramp followed by expiration and is produced by a lesion affecting the dorsolateral part of the tegmentum and dorsal pontine nuclei, e.g., thrombosis of a branch of the basilar artery. It is usually not seen with herniation, as the latter tends to produce medial brain stem lesions.

Cluster breathing occurs with high medullary lesions and is characterized by a burst of rapid irregular respirations followed by irregular shallow breathing or apnea. Duration of the interval between rapid and slow breathing may be irregular. Sometimes very deep gasps occur, usually before respirations cease altogether and death supervenes.

Ataxic breathing is a completely irregular pattern with deep and shallow breaths occurring randomly. The rate is slow. This type of breathing is caused by lesions which disrupt reciprocal pathways between inspiratory and expiratory neurons in the medulla. In this state, depressant drug hypersensitivity exists and a sedative may produce apnea. Hence, when this breathing pattern is noted, one must be extremely cautious with use of sedatives and analgesics which depress respiration.

What is the Size and Reactivity of the Pupils?

Pupillary size depends on both sympathetic and parasympathetic influences. The anatomy of the autonomic pathways may be summarized as follows: The *sympathetic* pathway sequentially traverses the hypothalamus—tegmentum—thoracolumbar spinal cord—sympathetic rami—sympathetic ganglia—sympathetic chain—ciliary ganglion (without synapse) to end in the radial fibers of the pupil. Pupillary dilatation (mydriasis) results.

The *parasympathetic* pathway may be traced from the pretectal nuclei—Edinger-Westphal nucleus—III nerve—to the ciliary ganglion where a synapse occurs. Thence, the postganglionic fiber passes on to the circular fibers of the pupil and causes pupillary constriction

†See Test Your Word Score Page 1213.

TABLE 3
PUPILLARY FINDINGS OF LOCALIZING SIGNIFICANCE

Site of lesion	Pupillary findings
1. cerebrum	non-specific
2. hypothalamus	constricted
3. midbrain	
a. pretectum	light reflex negative; ciliospinal reflex positive
b. nuclei	negative to all stimuli
c. III nerve	dilated pupil fixed to light directly and consensually; ciliospinal positive opposite side
4. pons	constricted (pin-point constriction means brain-stem hemorrhage)
5. lateral medulla	Horner's; light reflex positive
6. peripheral III	dilated (may be compressed against tentorium or posterior cerebral artery)

Note: If neck flexion gives dilatation of pupils suspect impending herniation.

(miosis).

Reflexes of clinical importance which involve the pupil consist of the light reflex and the ciliospinal reflex. The pathway of the *light reflex* involves optic nerve—optic tract—diencephalic pretectum—Edinger-Westphal nucleus bilaterally—III nerve—ciliary ganglion—to the circular fibers of the pupil. Miosis is produced on the ipsilateral and contralateral sides (direct and consensual reflex).

The *ciliospinal reflex* consists of an ipsilateral dilatation of the pupil to a noxious stimulus. Its anatomy involves a direct pathway from hypothalamus to the sympathetic system which causes active mydriasis and an indirect pathway which passes up the midbrain to inhibit the Edinger-Westphal nucleus. The ciliospinal reflex disappears with brain stem damage. Pupillary findings of localizing significance are listed in Table 3.

It is helpful to be aware of the effects of various drugs on the pupillary responses. Atropine causes dilatation by blocking parasympathetic influence. The block allows sympathetics to take over and dilatation of the pupils results. Pilocarpine is a parasympathomimetic drug and hence causes constriction like parasympathetic stimulation. Doriden (glutethimide) results in pupils which are fixed to light, irregular, and unequal. Opiates produce pin-point pupils, but bright light may still induce a pupillary response. Anoxia causes dilatation of the pupils.

How Do the Eyes Move?

Conjugate eye movements depend on complex interactions among 12 eye muscles. The movement of each eye in a particular direction is controlled by a pair of muscles. For example, abduction of the right eye involves contraction by the right lateral rectus and relaxation of the right medial rectus. The action of the superior and inferior recti and the superior and inferior oblique muscles may be thought of as stabilizers during abduction; they are certainly not passive. A thorough understanding of how the eye muscles work is essential to an understanding of eye movements. Here, however, the neurological control mechanisms will be emphasized.

One supranuclear control mechanism involves the frontal cortex (area 8) and is concerned with voluntary eye movements. Another involves the occipital cortex and subserves visual fixation. A third is believed to be centered in the parietotemporal region and controls opticokinetic movements. An internuclear mechanism exists which coordinates the conjugate movements of the eyes. It involves the medial longitudinal fasciculus. A vestibular contribution to eye control is derived from receptors in the semicircular canals which detect rotation, acceleration and deceleration. The fastigial nuclei of the cerebellum also serve to modulate eye movement. Finally, proprioceptors from neck muscles influence eye movements and account for the oculocephalic reflex about which more will be said later.

In order to evaluate extraocular movements, note should be taken first of the resting position of the eyes. Normally the eyes should be in a neutral position. Use of the light reflected from the cornea helps detect the presence of strabismus. If the head is rotated rapidly, the eyes seem to lag behind and deviate in a direction opposite to the head movement, like a doll's. The "doll's eye phenomenon" is not elicited in the normal individual. It constitutes the oculocephalic reflex.

Caloric stimulation also causes the eyes to deviate. Ice water may be instilled into the external ear after checking the intactness of the tympanic membrane and cleaning out cerumen. If the patient is supine, the head is tilted 30 degrees forward. If the patient is in the sitting position, the head is tilted 60 degrees backward. These positions will bring the lateral semicircular canal into vertical alignment and permit convection currents induced by the cold water instillation to stimulate the labyrinth.

Localization of lesions using eye movements are summarized in Table 4.

Eyes in the neutral position have no localizing value. With conjugate horizontal deviation, the lesion is usually in the cerebral hemisphere toward which the eyes deviate. The patient is "looking at the lesion." This holds true if the eyes are fully deviated and the doll's head maneuver yields deviation beyond the midline. However, if the eyes are only partially deviated, and head rotation fails to cause deviation beyond the midline, then the lesion is in the brain stem on the side opposite the direction of the deviation. The patient is

"looking away from the lesion." With conjugate downward deviation, the lesion is causing mesencephalic compression (setting sun sign), or there is mesencephalic metabolic depression. If the doll's eye maneuver produced by tilting the head downward produces deviation above the midline, then the lesion is metabolic. If eye deviation in response to head tilting is incomplete, then the lesion is anatomic.

What Movements Occur in the Limbs and Trunk?

Gegenhalten (paratonic resistance) consists of passive, plastic-like resistance of the extremities. The examiner has the impression that the patient is not cooperating. A grasp reflex and a positive Babinski may be found on the side of the lesion. This movement abnormality may be caused by a lesion in the frontal lobes. It is an early sign and may indicate the presence of diffuse vascular disease, metabolic disease, or a tumor.

The *response of the limb to noxious stimuli* is important. The response may be an appropriate withdrawal, which indicates that sensory pathways and motor pathways are at least partially intact. If the response to noxious stimuli is absent on one side, it indicates destruction of the corticospinal system or the spinothalamic system on that side. If bilaterally absent, deep coma, bilateral corticospinal damage, or a pontomedullary lesion should be suspected. If the response to noxious stimuli is inappropriate, one may see decorticate or decerebrate rigidity rather than appropriate withdrawal.

Decorticate rigidity may be recognized by the following features: the upper limb shows adduction with flexion at the elbow, wrist, and fingers. The lower limb is held in extension and is usually internally rotated with feet in plantar flexion. Decorticate rigidity results from damage to a frontal lobe or the thalamus.

Decerebrate rigidity consists of opisthotonus, clenched teeth, extended, adducted and hyperpronated arms with extended legs, and feet in plantar flexion. Experimentally, decerebrate rigidity is associated with lesions in the midpons which spare the vestibular nuclei and

TABLE 4
EYE POSITION AND MOVEMENTS RELATED TO SITE OF LESION

State	Eye Position	Involuntary Eye Movement	Oculocephalic Reflex	Response to Caloric Stimulation
1. Awake—no lesion	neutral	none	none	nystagmus

Syndromes of Progressive Impairment

Two clinically distinct syndromes of progressive impairment of consciousness have been recognized by Plum and Posner.[1] The first reflects bilateral progressive impairment of the diencephalon and brain stem and is called the *central syndrome*. The second is due to third nerve and lateral midbrain compression and is called the *uncal syndrome*.

Central Syndrome

The central syndrome is more common (Tables 5 through 8). In its early stages, consciousness is impaired. The patient is restless or somnolent. Respirations are interrupted by yawns, sighs and pauses but are otherwise regular. The doll's head maneuver elicits brisk eye movements which are not seen in a fully alert patient. Caloric stimulation produces conjugate deviation of the eyes, and limb movements may be appropriate, or gegenhalten is present on the ipsilateral side.

At a lower stage of diencephalic function, the patient is stuporous. Cheyne-Stokes respirations are present. The pupils are small but reactive. The ciliospinal reflex is present and the oculocephalic reflex is brisk. The installation of cold water into the ear produces conjugate deviation of the eyes, and movements of the limbs may be impaired. A grasp reflex may be elicited or contralateral decerebrate rigidity may be found. Ipsilaterally, there is a decorticate response, and a bilateral Babinski response may be present.

With involvement of the midbrain and upper pons the patient lapses into coma. Respirations may still be of the Cheyne-Stokes variety or central hyperventilation may be present. The pupils are dilated and unreactive. The ciliospinal reflex is lost. The oculocephalic reflex may be incomplete and sluggish, and the oculovestibular reflex elicits only partial eye deviation. Disconjugate eye movements may be noted, and the abducting eye moves better than the adducting eye. Decerebrate rigidity of the limbs is present.

At still lower levels of involvement of the brain stem involving pons and upper medulla, the patient is deeply comatose. Respirations are rapid and shallow or irregular. The pupils are dilated and unreactive. Ciliospinal, oculo-

7. Movements	ipsilateral hemiplegia (Kernohan's notch)	bilateral Babinski decerebrate rigidity

cephalic, and oculovestibular reflexes are absent. There are no spontaneous movements, but strong stimuli may elicit decerebrate rigidity.

Uncal Syndrome

The uncal syndrome is caused by herniation of the medial portion of the temporal lobe over the free edge of the tentorium. This movement of the temporal lobe often causes compression of the brain stem and may result in a bypass of the progressive stages of the central syndrome.

In the early stages of the uncal syndrome, the patient is quite alert and respirations are normal (Table 9). Anisocoria is a key sign and pupillary dilatation may be evident on the ipsilateral side. Occasionally the ipsilateral pupil is smaller than the contralateral pupil, perhaps because of irritation of the third nerve. The reaction to light on the ipsilateral side may be sluggish. Ciliospinal, oculocephalic, and oculovestibular reflexes are intact although they may be impaired on the ipsilateral side. One may occasionally find ipsilateral hemiplegia because a shift of the brain stem brings the contralateral pyramid up against the tentorium. Since at this point the pyramid has not yet decussated, hemiplegia is found on the ipsilateral side (Kernohan's notch phenomenon).

The patient may pass rapidly from the early to the late uncal stage. He may suddenly become comatose. Respirations may be irregular or central hyperventilation may be found. Occasionally, respirations are of the Cheyne-Stokes variety. The ipsilateral pupil is dilated and does not react to light. Ciliospinal, oculocephalic and oculovestibular reflexes are active ipsilaterally. Bilateral Babinski signs are elicited and there may be decerebrate rigidity.

It is very important to recognize the uncal syndrome in its early stages and institute therapeutic measures at this time. Prognosis is very poor in the late stage of the uncal syndrome.

Summary

Examination of a comatose patient requires a frame of reference regarding common etiologies. These include: impairment of oxygen supply to the brain, impairment of glucose supply, enzyme disturbances, and multiple etiologies. In examining the comatose patient, special attention should be paid to the level of consciousness, the respirations, the pupillary responses, the eye movements and the motor phenomena. A schema for recognizing the stage of coma using these parameters is provided and differences between the central and uncal syndromes are discussed. Familiarity with the points stressed here should help the clinician in managing the comatose patient.

Osteomyelitis Infection

In my early days with Doc another case came along which taxed my faith in him to the utmost, and eventually proved him to be more right than he knew.

Jake Wirt was a farmer, in his early thirties, living on the outskirts of a tiny village. While he was fixing a ridge on a silo he slipped and fell to the ground, smashing the distal bones of one leg into several fragments, some of which pierced the skin and caused an angry-looking gash. A neighborhood doctor who was called in put the injured leg up in the usual box without ends, and traction pully weights at the foot of the bed. A week elapsed before we were asked, in consultation, to see the leg. The dressing on the wound had not been changed, and Jake was very ill. I was asked to remove the dressing. The odor was almost unbearable.

I lifted off the last piece of gauze very carefully, and there lay before me a sight which both shocked and frightened me. The whole exposed, deeply lacerated surface, about the size of a dollar bill, was alive with squirming, wiggly, juicy maggots!

"Quick!" I cried, "hand me that ether out of my bag and get hot water, soap, and a brush ready. This is unthinkable. Why was this allowed to occur?"

As I prepared to clean up the mess, Doc stepped forward and said calmly, "Wait a minute, Son. Don't get nervous over a few maggots; and don't disturb them until we figure out the reason why they are there."

I stood dumbfounded. If it had not been for the many times he had spiked my medical guns, I would have considered him out of his mind.

In his deliberate, pensive manner, he went on: "Maggots are harmless. Deadly bugs that can destroy bone can destroy life. If the bugs conquer the maggots, the patient will die. If the maggots conquer the bugs, the patient will live. Leave the maggots to their destruction, or to their victory."

I was incredulous. "You think the maggots will eat up the infective germs and clean the wound?"

"That's right. The survival of the fittest."

I was not at all convinced, and thought I should have to sign Jake's death certificate in twenty-four hours. Doc took pity on my consternation, and sympathetically assured me that he would take all responsibility for the young man's life and leg, and suggested that I wait a while before I adversely criticised the incomparable defense forces of Nature.

"And don't think I'm gambling with a man's life, Son. Maggots have saved a lot of legs for me, and they will for you."

Old Doc took care of Jake. Months went by, and the leg was never discussed. One day Doc, with a sly look in his eye, said, "You recall Jake Wirt with the leg?"

"Yes," I said, impertinently, "When did you bury him?"

He laughed heartily. "Don't be too hard on the maggots. Jake will be in tomorrow, and I want you to graft a little skin on a small area that won't heal."

The next day I was speechless when Jake walked in, as normal as anyone. His leg had united firmly, and a square inch of added skin made a complete cure.

Twenty years later the cure of osteomyelitis by maggots was reported in medical literature.*

Vertebral–Basilar Insufficiency*

ARTHUR C. KLASSEN, M.D.†
Minneapolis, Minnesota

CENTRAL NERVOUS SYSTEM disorders due to cerebrovascular disease may conveniently be classified into those related to either the internal carotid arterial system or the vertebral-basilar arterial system. In either system, cerebrovascular syndromes of the atherosclerotic-thromboembolic type may present as:

(1) transient ischemic episodes,
(2) progressive strokes, and
(3) completed strokes.

This paper will be limited to a discussion of "vertebral-basilar insufficiency." The term refers to the mechanism of production of transient ischemic episodes in the vertebral-basilar system.

During the late 19th and early 20th centuries, a plethora of brainstem and cerebellar vascular syndromes (Wallenberg,‡ Weber's, Millard-Gubler syndromes, etc.) were described. These have most recently been organized and classified by Fisher.[1] In general, it was felt that these characteristic clinical syndromes were due to thrombotic occlusion of specific arteries, e.g., the posterior inferior cerebellar artery, etc. These reports led to a thorough study of brain-stem vascular anatomy and to pathological-clinical correlations of specific lesions.

Kubik and Adams[2] in 1946 emphasized that many of their patients with basilar artery occlusion had experienced transient symptoms, probably related to narrowing of the basilar artery, which could be recognized long before the final fatal occlusive event.

Further observations by Denny-Brown in 1953,[3] and Millikan and Siekert in 1955[4] led to the concept of "intermittent insufficiency of the basilar arterial system." This concept carries with it the implication of transient and intermittent symptomatology related to dynamic changes in blood flow in the vertebral-basilar arterial system.

Incidence

In the past decade it has become increasingly obvious that this syndrome is indeed very common. Approximately five to 10 per cent of all patients with clinical cerebrovascular disease will have symptoms primarily of vertebral-basilar insufficiency. It is seen at least as frequently as carotid insufficiency. In at least 50 per cent of patients with completed stroke syndromes of the vertebral-basilar type, a history of episodic vertebral-basilar insufficiency preceding the completed stroke may be elicited.

The frequency with which patients manifesting symptoms of vertebral-basilar insufficiency develop completed stroke syndromes (catastrophic or less severe) is unknown. Earlier reports placed the incidence of subsequent infarction in patients with insufficiency as high as 50 per cent. More recent studies by Marshall in 1964[5] suggest that only five to 10 per cent of patients with vertebral-basilar insufficiency eventually develop completed stroke syndromes in the same arterial distribution. However, it is the impression of many clinicians that the latter figure is too low. At any rate, patients with symptoms of vertebral-basilar insufficiency often develop subsequent completed stroke syndromes, usually involving the same central nervous system structures as were affected during the episodes of insufficiency.

Circulatory Factors

Dynamic alterations in cerebral blood flow and perfusion of central nervous system tissue by blood are felt to be directly responsible for the production of episodic neurological dysfunction in these structures. If the period of relative ischemia (or hypoxia) is brief (seconds to several minutes), function may return quickly and completely. If more prolonged ischemia occurs, infarction will usually result.

Anatomical variations in the vertebral and basilar arteries and their branches occur fairly frequently. The right and left vertebral arteries usually arise as the first major branches of the proximal subclavian arteries. In about five per cent of individuals the left vertebral artery arises directly from the arch of the aorta. The two vertebral arteries are frequently of unequal calibre, and occasionally one vertebral artery may be a very slender thread-like vessel. The vertebral arteries ascend through foramina within the transverse processes of the upper six cervical vertebrae, enter the intracranial cavity through the foramen magnum along the anterior aspect of the medulla and, at the level of the upper medulla or lower pons, unite to form the basilar artery. The basilar artery in turn lies along the anterior surface of the pons and, at the junction of pons and mid-brain, it divides into the right and left posterior cerebral arteries. The proximal posterior cerebral arteries are connected to the internal carotid arteries by the posterior communicating arteries, thus completing the posterior half of the "circle of Willis." The posterior communicating arteries are often very small or thread-like. In about 15 per cent of individuals the posterior communicating on at least one side is very large and represents the major source of blood flow to the corresponding posterior cerebral artery.

Under normal circumstances there is thought to be virtually no cross-circulation between the basilar and carotid arterial systems. It can be appreciated that localized obstructions to flow in the various vessels feeding the circle of Willis may lead to changes in the dynamics of flow in the circle.

Each of the major arteries and their branches supply a fairly consistent portion of the brain stem, cerebellum, and posterior cerebral hemispheres (Table 2).

Aside from the circle of Willis, other sites of potential or actual anastomosis are present within the vertebral-basilar system or between this system and the carotid arterial system. These anastomoses are located between the following vessels:

(a) Superior thyroid artery (branch of external carotid) and muscular branches of vertebral arteries in the neck.

(b) Anterior spinal artery and medullary radicals of the segmental vertebral branches.

(c) Occipital artery (external carotid

branch) and muscular branches of vertebral arteries.

(d) Superior cerebellar and posterior inferior cerebellar arteries.

(e) Temporal branches of middle cerebral and posterior cerebral arteries.

(f) Anterior cerebral and occipital branches of posterior cerebral arteries.

(g) Anterior and posterior choroidal arteries.

(h) Internal carotid and basilar arteries via occasional primitive trigeminal and hypoglossal arteries.

It is estimated that approximately 10 per cent of total cerebral blood flow occurs via the vertebral arteries under normal circumstances. However, quantitative measurements of flow in the vertebral-basilar system in any given individual are performed with great difficulty, and the circulatory effects of vascular occlusion at any point in the posterior circulation are quite impossible to predict. It is also quite possible that flow in the vertebral-basilar system may be more directly related to systemic blood pressure and less influenced by arterial pH and pCO_2 than is flow in the carotid arterial system.

Etiological Factors

The most important etiologic factors (Table 1), in terms of frequency of occurrence, are those causing reduction in size of the lumen of the vertebral or basilar arteries, or reduction in systemic blood pressure and cardiac output.

Related to Blood Vessel Wall or Lumen

Atherosclerosis of both the extracranial vertebral arteries and of the intracranial vertebral-basilar system and its branches is by far the most common cause of luminal encroachment. Sites of predilection for the formation of atherosclerotic plaques are located at the origin of the vertebral arteries, at the sites of entry of the vertebral arteries into the vertebral foramina and into the subarachnoid space, at the junction of the vertebral arteries to form the basilar artery, in the upper basilar artery and its bifurcation, and along the proximal portions of the posterior cerebral arteries. Smaller branches are less often the site of atherosclerotic plaques. The resulting pattern of narrowing and occlusion of these arteries may thus be very complex. In addition, atherosclerotic narrowing of the proximal subclavian arteries before the origin of the vertebral arteries may also cause decreased or even reversed flow in the vertebral arteries. This syndrome of "subclavian steal" will be discussed later.

Less common causes of vertebral artery narrowing, usually by external compression, are also listed in Table 1. It is felt that cervical *spondylosis with osteoarthritic compression* of the vertebral arteries in the neck may be a significant factor in many patients whose symptoms are precipitated by neck movements. The other causes listed have been implicated in individual cases. The significance of compression of the arteries in the neck by fibrous or muscular bands is open to question, as is the significance of excessive kinking or loops in the vertebral arteries.

Intermittent *decrease in collateral blood flow* through any of the multiple anastomotic channels could produce transient ischemia in the presence of a fixed stenotic lesion in the vertebral-basilar system. It has been postulated that *embolization* from adherent thrombi located in the proximal vertebral arteries, especially in the neck, may well be one of the most common causes of transient ischemic episodes. Although pathological proof of this postulate

drug induced
blood loss, etc.
cardiac origin
C. *Related to Blood:*
severe anemia
polycythemia
D. *Other:*
chronic or acute pulmonary disease
hypoglycemia

is lacking, it is certainly a very strong possibility. The analogous production of "amaurosis fugax" (intermittent monocular visual loss) in internal carotid artery stenosis is almost certainly due to embolization in many instances.

Related to Blood Pressure

Under normal circumstances the total and regional cerebral blood flow remains remarkably constant despite marked fluctuations in the systemic blood pressure. However, it has been frequently observed that patients may develop symptoms of vertebral-basilar insufficiency under circumstances of hypotension or decreased cardiac output due to a variety of causes. Drug-induced relative hypotension, often during the course of treatment of mild to moderate hypertension, is a common cause. Intermittent decrease in cardiac output, possibly due to transient arrhythmias or myocardial ischemia is frequently implicated.

Changes in the blood, such as decreased oxygen-carrying capacity (severe anemia) and increased viscosity (polycythemia) have been reported in association with episodic vertebral-basilar insufficiency. Other causes of relative hypoxia, such as pulmonary disease, or disturbed brain cell metabolism (as in hypoglycemia) may also precipitate identical symptoms.

The mechanism of production of symptoms in the so-called "subclavian steal syndrome" may conveniently be discussed at this point. This subject was thoroughly reviewed by Patel and Toole in 1965.[6] In general, it has been demonstrated that arterial obstruction in strategic locations may cause reversal of normal arterial pressure gradients and actually cause blood to flow in a reverse direction. When the subclavian artery proximal to the origin of the vertebral artery is markedly narrowed or occluded, blood flow in the ipsilateral vertebral artery may actually be in a reverse direction and be a major source of blood to the arm via the distal subclavian and brachial arteries. The arm may thus be supplied with blood at the expense of the vertebral-basilar system, giving rise to symptoms of vertebral-basilar insufficiency.

While atherosclerosis of the proximal subclavian artery has been found to be the most common cause of the "subclavian steal" syndrome, other rare causes have been noted, such as coarctation of the aorta, congenital subclavian atresia, giant cell arteritis, trauma with subintimal dissection of the subclavian artery, and an aftermath of the Blalock-Taussig procedure.

Cardiac Abnormalities

Ischemic or valvular heart disease may be a major cause of cerebral ischemic symptoms due to intermittent and transient drops in cardiac output, related to either myocardial

TABLE 2

Symptoms And Signs of Vertebral-Basilar Disease

Structure And Arterial Supply	Symptoms And Signs
A. *Medulla and Upper Cervical Spinal Cord.* [anterior spinal artery, posterior inferior cerebellar arteries, small vertebral artery branches.]	Dysarthria and dysphagia Weakness or paresis all 4 limbs Drop attacks Hypalgesia—unilateral or bilateral Vertigo, nausea and vomiting Ataxia Horner's syndrome Facial dysesthesias

C. *Labyrinth and Cochlea* (?) [internal auditory artery.]	Vertigo, nausea and vomiting Tinnitus Acute onset deafness
D. *Pons and Midbrain.* [basilar and proximal posterior cerebral arteries]	Light headedness and/or syncope Confusion, stupor or coma Diplopia and ocular palsies Hypalgesia and weakness—unilateral or bilateral Paroxysmal hypertension Headache, suboccipital
E. *Thalamus and Subthalamus* [posterior cerebral artery.]	Thalamic syndrome Anesthesia dolorosa Tremor Hemiballism
F. *Cerebral Hemispheres — Occipital and Temporoparietal.* [posterior cerebral artery.]	Visual field defects Teichopsias and visual hallucinations Cortical blindness Focal cerebral deficits, [aphasia, dyslexia, visual agnosia, etc.] Temporal lobe seizures

ischemia or arrhythmias.

Clinical Manifestations

The symptoms and signs in vertebral-basilar insufficiency[7,8,9] may be easily and closely correlated with the function of those neural structures rendered temporarily ischemic (Table 2).

The *frequency* with which these episodes of insufficiency occur in the individual patient may vary greatly. The *duration* of this episodic neurological dysfunction is usually measured in minutes. It may persist for several hours but, by definition, must be of less than 24 hours' duration.

The most frequent symptom complex encountered is probably that of *vertigo* (with or without a sense of faintness), often with some *visual disorder* (visual field defect, hallucination or diplopia) and some evidence of localized *brain stem dysfunction* (dysarthria, dysphagia, facial dysesthesia, etc.).

Vertigo

This symptom is present in two thirds of the patients and may vary in intensity from minimal disability to severe prostration. It is usually not accompanied by tinnitus and hearing loss. It is often aggravated by movement of the head, eyes, or neck, or by body position changes.

Visual Disorders

As an isolated symptom, "spots in front of the eyes" may be the most common but is frequently ignored by the patient. Teichopsias of various types (black or white spots, "floaters", wavy lines) are described by about one half of patients. More complexly formed hallucinations such as zig-zag lines, coloured lights and patterns, and even formed coloured objects may occur. Visual field defects are less common and consist of homonymous or bilateral hemianopsias or quadrantanopsias. Visual illusions and distortions (e.g., "seeing through water") also occur.

Visceral Sensations

Nausea and vomiting are common. Patients may have flushing and sweating and experience choking thoracic sensations or feelings of impending doom. Some of these symptoms may resemble temporal lobe or diencephalic seizures.

Drop Attacks

Sudden unpredictable falling to the ground without loss of consciousness occurs in about 15 per cent of patients and is virtually pathognomonic of vertebral-basilar insufficiency.

Headache

Headache is a prominent symptom in about 10 per cent of patients. The pain is often intense, is usually located in the occipital or suboccipital area, and is generally throbbing in quality and aggravated by change in position. It may be accompanied by neck stiffness and occipital tenderness. Occasionally the headache may be unilateral in any part of the head, and the combination of severe headache with visual disturbance and severe nausea may resemble migraine.

Disturbance of Consciousness

Disturbance of consciousness occurs at some time in about one third of patients but is usually mild and transient, such as a brief clouding of consciousness. Syncope may occur due to brain-stem ischemia and occasionally may be followed by a seizure. Loss of consciousness without any other symptom or sign does not occur in vertebral-basilar insufficiency.

Hemiparesis

Hemiparetic symptoms are uncommon and when present are usually transient and minor. If recurrent, the paresis often fluctuates from side to side or involves both sides simultaneously. Occasionally, a quadriparesis with pseudobulbar symptoms may occur. *Sensory symptoms,* especially dysesthesias around the mouth, scalp, and neck, are common.

Differential Diagnosis

In the evaluation of symptoms and signs of vertebral-basilar insufficiency it is important that the diagnosis of *"subclavian steal"* be considered and looked for specifically. These patients may complain of symptoms of vertebral-basilar insufficiency precipitated by exercise of the arm on the same side (and occasionally of the contralateral arm). They may also complain of arm symptoms such as claudication, tingling, or numbness on exercise of the limb.

Significant *signs* of the "subclavian steal" syndrome are:

1. A decrease in radial pulse and in systolic

blood pressure of more than 20 mm. mercury on the affected side. This disparity in pulse and blood pressure may be more marked when erect or after exercise of the arm.

2. A delay in the time of appearance of the radial pulse on the affected side is pathognomonic of the syndrome.
3. A bruit may be audible over the vertebral or subclavian arteries, usually on the same side.

This syndrome should be recognized; as it represents a potentially treatable cause of vertebral-basilar insufficiency. However, it must also be stated that the natural history of these lesions is not yet known and spontaneous remissions of symptoms may occur.

Many other disease processes, as listed in Table 3, may mimic the symptoms and signs of vertebral-basilar insufficiency. Of these, Meniere's syndrome may be one of the most difficult to differentiate. It is, however, usually of much longer duration and often accompanied by tinnitus and hearing loss.

Angiography

Angiographic visualization of the vertebral and basilar arteries in the presence of significant atherosclerotic disease in these vessels may occasionally cause infarction of the central nervous system tissues supplied by these arteries. Angiography should, therefore, be undertaken only when:

(a) an intracranial surgically-correctable lesion must be ruled out,
(b) a correctable vascular lesion is probably present, (e.g., "subclavian steal"), or
(c) incapacitating insufficiency is present which does not respond to medical management.

Treatment

The primary aim of treatment is to prevent further episodes of vertebral-basilar insufficiency and, hopefully, to prevent the development of infarction of tissue in the same arterial distribution.

Meticulous attention should be paid to all possible etiological factors and other possible diagnoses, as listed in Tables 1 and 3.

Blood Pressure

The blood pressure should be watched carefully and the effects of rapid postural changes on blood pressure should be noted. Always check the blood pressure in both arms. If the blood pressure appears excessively high, that is, with diastolic pressures greater than 110-120 mm. mercury, attempts should be made at gradual lowering of the blood pressure. It should be noted, however, that some patients first develop symptoms of insufficiency after even modest antihypertensive therapy. It is possible that some patients with vertebral-basilar insufficiency need a slightly elevated blood pressure for adequate perfusion to occur. Therefore, moderate hypertension should not be vigorously treated in the face of this clinical picture. However, if there is any suggestion of even moderate postural hypotension as indicated by symptoms or actual blood pressure measurements, a trial of elastic leg bandages or stockings and even an abdominal binder or girdle should be instituted.

Severe *anemia* should be corrected if present. *Polycythemia* may also give rise to transient symptoms.

Anticoagulants

Anticoagulation therapy probably represents the treatment of choice if other general medical measures do not result in cessation of these episodes. It should be stated, however, that the final answer regarding the efficacy of anticoagulant therapy in the treatment of cerebrovascular disorders, including vertebral-basilar insufficiency, is not yet available. At the present time, it would appear that the best response to anticoagulant therapy in the treatment of cerebrovascular disease is seen in patients with

TABLE 3
Differential Diagnosis Of Vertebral-Basilar Insufficiency

Carotid insufficiency
Meniere's syndrome
Acute labyrinthitis
Cerebellopontine angle tumor
Cerebellar tumor—especially metastatic
Hypotensive episodes
Carotid sinus sensitivity
Hypoglycemic attacks
Drug intoxication—especially barbiturates
Migraine
Hyperventilation syndrome
Multiple sclerosis

insufficiency or progressive infarction in the vertebral-basilar system. Some reports have demonstrated a marked decrease in the incidence of subsequent ischemic episodes while on anticoagulants, while other studies have shown a very minor or no decrease in the frequency of episodes. Despite these inconsistencies, it is the consensus of many, but not all neurologists, that anticoagulation should be used, often as an emergency measure, in patients with insufficiency or progressive stroke in the vertebral-basilar system.

Patients that appear to respond best to anticoagulant therapy are those who have experienced many episodes within a relatively short period of time. It is possible that these patients represent embolization from thrombi in the proximal neck vessels.

The usual precautions regarding anticoagulant therapy will, of course, prevail. Lumbar puncture should be performed prior to institution of therapy to rule out intracranial and subarachnoid hemorrhage. Modest hypertension has not usually been considered a contraindication but may be treated concomitantly (but cautiously!). The coumarin compounds are used routinely, although in occasional cases where progressive infarction is apparent or seems imminent, heparin may be used to initiate therapy.

IT'S THE LAW

No Liability for Hepatitis Following Transfusion

A hospital and surgeon won a verdict in a suit by an Illinois trial court. A patient, who developed serum hepatitis following transfusion of two pints of blood during the course of an operation, was denied compensation. The infection was held to be a calculated risk of blood transfusion.

An expert witness for the surgeon and for the hospital testified that there is no known test whereby the presence of hepatitis virus can be detected. The director of the blood bank testified that the virus occurs in 0.3 per cent of blood donors, and that hepatitis is a calculated risk in blood transfusion.

Ronald Ross 1902

For his work on malaria, by which he has shown how it enters the organism and thereby has laid the foundation for successful research on this disease and how to combat it.

"Towards the middle of August (1897) I had exhaustively searched numerous grey mosquitoes and a few brindled mosquitoes. The results were absolutely negative; the insects contained nothing whatever.

"I had remembered the small dapple-winged mosquitoes (genus Anopheles), but as I could not succeed either in finding their larvae or in inducing the adult insects to bite patients, I could make no experiments with them. On the 15th of August, however, one of my assistants brought me a bottle of larvae, many of which hatched out next day. Among them I found several dapple-winged mosquitoes, evidently of the same genus as those found about the barracks, but much larger and stronger. Delighted with this capture I fed them on a case with crescents in the blood."

After unsuccessful dissection and examination of six of these insects Ross had only two left.

"The seventh dapple-winged mosquito was then successfully dissected. Every cell was searched, and to my intense disappointment nothing whatever was found, until I came to the insect's stomach. There, however, just as I was about to abandon the examination, I saw a very delicate circular cell apparently lying among the ordinary cells of the organ, and scarcely distinguishable from them. Almost instinctively I felt that here was something new. On looking further, another and another similar object presented itself. I now focussed the lens carefully on one of these, and found that it contained a few minute granules of some black substance exactly like the pigment of the parasite of malaria . . . After mounting the preparation I went home and slept for nearly an hour. On waking, my first thought was that the problem was solved; and so it was.

"The next morning the eighth and last dapple-winged mosquito was killed and dissected with much anxiety. *Similar bodies were present in it.* The objects lay, not in the stomach cavity of the insects, but in the thickness of the stomach wall.

"These two observations solved the malaria problem . . . At a stroke they gave both of the unknown quantities—the kind of mosquito implicated and the position and appearance of the parasites within it."*

*With acknowledgments to Theodore Sourkes: Nobel Prize Winners in Medicine and Physiology, 1966.

Oof Da!

Medicine must have been much simpler in the time of John of Mirfield, when, according to him, successful physicians required only three special qualities: "to be able to lie in a subtle manner, to show an outward honesty, and to kill with audacity."*

Brain Abscess *

ZONDAL MILLER, M.D.
St. Paul, Minnesota

SUPPURATION IN THE intracranial cavity results in meningitic, encephalitic reactions and brain abscess formation. When a neurologist or neurosurgeon first sees the patient, rarely is it evident that a brain abscess exists unless it is known the patient has previously been diagnosed as having a purulent sinusitis, otitis media, mastoiditis, or a penetrating head injury. A diagnosis of a brain abscess caused by other than direct extension is most difficult to make, especially in our present antibiotic era, as there has been a decrease in the direct extension pathogenic cases and an increase in the metastatic forms. With the advent of effective antibacterial chemotherapy, the treatment of intracranial suppurative disease has been profoundly altered. Some of these diseases, for example, intracranial thrombophlebitis, bacterial meningitis, and certain cases of extradural abscess, can be managed entirely by the use of antibiotic medication. In others, such as subdural empyema and brain abscess, the use of antibiotics has greatly facilitated the treatment, even though the ultimate therapy is surgical.

In the pre-antibiotic era the mortality was approximately 50%. Prior to World War II, the mortality rate at Massachusetts General Hospital was approximately 80%, and from a period of 1946 to 1950 it was 34%. Other large groups have reported mortality figures of 45-80% prior to antibiotics, and a reduction to 30-40% in our present chemotherapeutic era. Problems in recognition and management of brain abscesses still remain a formidable problem. Furthermore, the patient who survives the surgical removal of a brain abscess may still be left with permanent neurologic disabilities.

Surgical intervention began with Macewen in 1880. The three major objectives in the treatment of a brain abscess are: (1) to save the patient's life, (2) to preserve or restore optimum neurologic function, (3) to prevent

*Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.

disabling sequelae such as epilepsy, aphasia, and hemiplegia.

Pathogenesis

With the exception of a relatively small number of cases (other than the large number occurring during armed conflict) in which infection may be introduced from the outside, for example, via penetrating missiles, compound fractures of the skull, and intracranial operations, the occurrence of a brain abscess is almost always secondary to a focus of suppuration elsewhere in the body.

Chronic Otitis Media

Prior to antibiotics, chronic otitis media accounted for somewhat more than half of all the cases of intracranial abscess formation. Even now it still may represent the most important cause. In these cases the abscess is most frequently found in the temporal lobe and next in the cerebellum; rarely does it occur in other parts of the brain or in multiple formation. The method of spreading is usually by direct extension, in which the roof of the tympanic cavity or mastoid bone becomes the nidus of osteomyelitis with secondary necrosis and perforation. The overlying dura becomes inflamed, with spread by way of the perivascular spaces. Thrombophlebitis of the pial veins and dural sinuses provides the mechanism for the formation of brain abscesses by blocking normal blood flow and causing infarction of brain tissue, which then renders this area more vulnerable to the infectious material. Experimental data in animals indicate that infarction of tissue is the most important factor in the development of brain abscess. The spread along venous channels also explains how a cerebellar abscess can develop from the contiguous phlebitis of the lateral sinus, and also how frontal lobe or parietal lobe abscesses may develop from the distant source of infection in the middle ear.

Infection of Nasal Cavity and Sinuses

Infections of the nasal cavity and accessory sinuses also constitute an important source for intracranial abscess formation; it has been estimated that approximately 20% of such abscesses have their origin from infected sinuses. The most frequently involved sinuses are the frontal, ethmoid, and sphenoidal. The inflammatory reaction tends to extend along the veins draining into the cavernous sinus with or without antecedent osteomyelitis.

Metastatic Infection

Over one third of brain abscesses are metastatic in origin, the most important sources being the lungs or pleurae (*thoracogenic*), and the heart (*cardiogenic*), and especially secondary to cases of congenital heart disease. However, on occasion, inflammation of the pelvic organs, abscessed teeth or tonsils, and osteomyelitis of non-cranial bones may metastasize to the cerebral hemispheres. Bronchiectasis is also a frequent source. Usually abscesses secondary to pleuropulmonary disease are multiple in over 40% of cases; the metastatic formation tends to affect the frontal, parietal, and occipital parts of the brain with about equal frequency, rarely involving the temporal regions or cerebellum. The heart is an important source of metastatic brain abscess formation due to either fragments of infected vegetation from the heart valves or because of congenital defects permitting shortcircuiting of the pulmonary circulation, thus allowing infected emboli to reach the vessels of the brain, causing infarction of the brain tissue with only a restricted inflammatory response about the involved vessel. Spinal fluid in these cases seldom shows more than a slight increase in the polymorphonuclears and, occasionally, some red blood cells.

It has been postulated that the chronicity of the viridans infection allows the central nervous system tissue to develop an immunity to the organism. However, an acute bacterial ulcerative endocarditis, the type frequently caused by staphylococcus, hemolytic streptococcus, or pneumococcus bacteria, which usually runs a fulminating course, frequently gives rise to multiple small abscesses of the brain, as it does to many other organs of the body. Approximately 5-10% of cases of *congenital heart disease* result in brain abscess, usually solitary, and rarely seen before the third decade.

Unidentified Cause

It should be emphasized that in a small portion, somewhere between 5-15%, a primary focus of infection cannot be found and may not be discovered even at autopsy. In a num-

ber of cases the primary source of infection appears only after a brain abscess has been recognized and successfully treated.

The organisms responsible for brain abscesses are remarkably diverse. An abscess may contain only a single organism; but more frequently several organisms are present. Those deriving from the middle ear or paranasal sinuses are the staphylococcus, streptococcus, and pneumococcus, but various anaerobic strains of streptococci, diphtheroid, and fusiform bacilli may also be present.

Metastatic abscesses are caused by an even greater variety of pathogens. Anaerobic streptococci are commonly found in abscesses secondary to congenital heart disease. Unusual abscesses may be due to typhoid bacillus, clostridium, and various fungal organisms such as actinomyces. In a number of cases the pus from an abscess will be sterile. Blood cultures show growth only in those cases associated with septicemia. As a rule, spinal fluid culture discloses no growth unless the abscess is associated with purulent meningitis, resulting from a rupture of the abscess. In those cases where more than one organism is found on culture of the spinal fluid, the physician should be alerted to the diagnosis of a brain abscess. The abscesses, as a rule, develop in the white matter, which has a poor blood supply in contrast to the cortex; and most of them originate just subcortically as an area of cerebritis with a necrotizing center that has a poorly defined inflammatory zone. Subsequently a variable capsule formation develops. When formed the capsule may be incomplete and the abscess may thereafter be unilocular or multilocular. It may continue to enlarge by thrombosis of the adjacent vessels and by secondary necrosis, usually in a direction toward the centrum, making it much more likely to rupture into the ventricles than into the subarachnoid space.

Diagnostic Consideration

The diagnosis of a brain abscess remains difficult and treacherous. Simple awareness that it may exist is of prime importance.

Headache

The initial symptom of intracranial infection is headache, the one symptom almost invariably present. The appearance of a headache or any neurologic symptom which cannot be explained by the known primary infection should always alert the doctor to the danger of an abscess formation; and he should be especially concerned regarding the development of an acute headache in individuals known to have congenital heart disease. Other presenting symptoms include profound lethargy, mental confusion, hyperirritability, stupor, nausea, emesis, and focal or generalized seizures. In most cases the headache is more severe on one side and tends to increase in severity as the disease progresses, though it may decrease as encapsulation occurs.

Neurologic Signs

Localizing neurologic signs appear sooner or later in almost all cases; but, like papilledema, they appear relatively late in the course of the illness, when it may be too late for instituting a successful therapeutic regime. Of course the nature of focal signs will depend upon the locality of the abscess. Whereas headache may be the most prominent feature in most patients, focal seizures may predominate in others, and still another group may present only with signs of increased intracranial pressure. The development of new neurologic signs is usually rapid. In a few cases the evolution is slower; and in those with an indolent course a mistaken diagnosis of a cerebral neoplasm is frequently made.

The more acute symptoms and signs are usually associated with the encephalitic reaction prior to encapsulation. With the latter, the patient tends to improve and the physician may be "red-dogged" into complacency. Subsequently, worsening may result from abscess rupture or the development of increased intracranial pressure and subsequent medial temporal lobe or cerebellar tonsil herniation.

Other Signs and Symptoms

Seizures occur in about the same frequency noted in large series of cerebral neoplasms, about 25-30%. Frequently the patient presents with predominant signs of *meningeal reaction,* and the half-diagnosis of meningitis or encephalitis is made. If focal signs occur with the meningo-encephalitic reaction, the diagnosis of brain abscess becomes easier. The patient with a brain abscess may show a *moderate temperature elevation* between 100-102° and a mild polymorphonuclear leukocytosis.

However, on occasion, particularly in those with chronic and encapsulated abscesses, there may be no fever, or the temperature may actually be below normal. In the average case, the cerebrospinal fluid pressure is moderately increased but is apt to be quite high in the more advanced cases. In the absence of generalized meningitis, the cell count may range from five to 300 cells, occasionally higher with the more acute cases having a predominance of neutrophils. In rare cases there may be only a few lymphocytes and in some cases no pleocytosis. The *spinal fluid protein* is almost invariably elevated, and spinal fluid sugar is not below normal unless there is an associated meningitis.

Diagnostic studies which are helpful include x-rays of the chest, skull, sinuses, and mastoids, readily available at any hospital. An electroencephalogram may be quite informative, especially for finding a delta focus in the presence of a meningo-encephalitic reaction. Other specialized procedures include brain scanning, angiograms, and air studies. Kahn, in 1939, recommended the injection of 2-3 cc. of thorotrast in the abscess cavity at the time of the initial aspiration. This material is taken up by phagocytes in the wall of the abscess so that subsequent x-ray study will reveal the size of the lesion and determine whether therapy has been effective.

Differential Diagnosis

A differential diagnosis of a brain abscess must include epidural abscess, subdural abscess, cerebral thrombophlebitis, focal embolic infarction, acute necrotizing hemorrhagic encephalopathy, primary and metastatic neoplasms, especially metastatic meningeal carcinomatosis and, occasionally, massive ischemic infarction. Extradural abscesses rarely reach sufficient proportion to cause increased intracranial pressure. Irregular fever, local headache, tenderness over the affected region, and a mild pleocytosis of the spinal fluid are its main manifestations.

Subdural empyema is a highly lethal complication of frontal osteomyelitis and sinusitis and is rarely secondary to chronic otitis media. As subdural pus accumulates over the frontal lobe, there is apt to be rapid progression of mental obtundency, stiff neck, stupor, and hemiplegia, with or without focal generalized seizures.

Intracranial thrombophlebitis is a frequent complication of suppurative meningitis, usually manifesting itself four to 10 days after the onset of meningitis by a burst of seizures, focal neurologic signs, and exacerbation of fever. The lateral, cavernous, and superior longitudinal sinuses are frequently affected by a spread of infection from the middle ear, skin of the face, or frontal sinus. All of these varieties are characterized by a high remittent fever.

Management of Brain Abscesses

The presence or absence of a brain abscess is ultimately determined by exploring the brain with a ventricular needle through a burr hold or craniotomy. This procedure not only confirms the diagnosis but constitutes the first step in treatment. The abscess is drained, and contrast material, along with a mixture of the broad-spectrum antibiotics, is frequently injected into the abscess cavity. Cultures of the pus are made to determine the appropriate antibiotic therapy, to be given orally or parenterally. Subsequent skull films are taken to determine the size and position of the lesion. The neurosurgeon may prefer to aspirate the septic focus repeatedly; others may totally excise the septic area after initial aspiration.

Repeated aspiration is the treatment of choice if the abscess is deeply located, poorly encapsulated, or situated in a strategic motor or speech area. Most surgeons, however, are reluctant to depend upon the effects of aspiration alone, since many abscesses may have multiple non-communicating loculi, only one of which is being tapped and visualized by the contrast material. In fact, while one abscess cavity is healing, another may be ripening for rupture. If the patient's condition permits, total excision of a well-encapsulated abscess is far less damaging to brain tissue than wide excision of a poorly demarcated area of suppuration. Metastatic abscesses are more progressive and malignant and less apt to form capsules due to the virulence of the organism and insufficient host resistance. The surgical treatment of such an abscess is a difficult and complex problem, and one that cannot be standardized for every patient. The most impor-

tant key to success is early recognition that an abscess exists.

Case Report

Case 1

A 33-year-old male was admitted to St. John's Hospital, March 4, 1961, with a history of flu-like symptoms and a mild fever for a week prior to admission. His wife was also treated for a flu syndrome. On the day of admission, the patient was drowsy, with a mild temperature of 99.4°, which subsequently became normal. He had a bradycardia, with a pulse ranging from 42-48. There was some questionable exposure to lead paint. He was first seen in consultation March 8 and was lethargic, though he could be aroused, whereupon he became hyperirritable. He did not communicate. Neurologic examination, in addition, revealed his pupils to be 3 mm. in diameter and equal. No papilledema was noted; eye signs were normal. There was mild neck rigidity and mild reflex changes with an increase in the left knee jerk and a decrease in the left cremasteric reflex along with a positive left Babinski. Laboratory studies performed prior to consultation disclosed a hemoglobin of 14.1 gm., a WBC of 9,000 with 68% polys, and a sedimentation rate of 62. Spinal fluid showed elevation of the cerebrospinal fluid pressure with a reading of over 500 mm. in the upright position. Spinal fluid analysis revealed 45 white cells with 97% lymphocytes, a protein of 101 mg. and a sugar of 33 mg. The working diagnosis was that of encephalitis. However, because of increasing stupor and the development of disconjugate eye movements, further studies were performed. Prior chest and skull x-rays had been normal. An angiogram on March 11, 1961, disclosed a large lesion in the left frontal area. At craniotomy, green pus with a fecal odor was encountered, and approximately two ounces of pus was drained. Subsequently, complete extirpation of the abscess and the capsule was accomplished. Postoperatively the patient was decerebrate, with a progressive downhill course and expiration March 29, 1961, 18 days after surgery. Culture of the purulent material revealed anaerobic streptococcus. Autopsy was not granted.

Comment: An original diagnosis of encephalitis became less evident as the patient showed increasing neurologic signs and symptoms, and as angiography disclosed, the mass lesion and abscess formation was found at craniotomy. This is a case of presumed metastatic source; however, the primary focus was not determined.

Case 2

A four-year-old child was admitted to St. John's Hospital, November 10, 1964. He had previously been treated for an upper respiratory infection but was not responding to antibiotic therapy, which included gantrisin orally. At the time of admission the patient was dehydrated and was vomiting. His temperature was 99.8° and shortly thereafter dropped to 97°. Later he was lethargic and difficult to arouse, and it was noted that he had a mild neck rigidity. His chest was clear, there were no heart murmurs, and ear- nose- and throat-examination was negative. Spinal tap five hours after admission disclosed clear, colorless fluids with 52 white cells, predominantly mononuclears, with a sugar of 62 mg. %, and a protein of 57 mg. %. Hemoglobin was 10 gm., WBC 10,500, with 84% neutrophils.

Shortly after spinal puncture the child developed flaccid paralysis and became comatose, with episodes of opisthotonus positive Babinskis, and then respiratory paralysis. He was maintained on a Bennett respirator for 12 hours, until expiration. Prior to death, the child had been seen by a neurosurgeon, who found no papilledema, equal pupils, and mild neck rigidity. The eyes were slightly deviated to the left, and there was unsustained bilateral clonus with a positive right Babinski. At autopsy an abscess was found in the right lobe of the cerebellum, coning of the cerebellar tonsils, and slight coning of the medial temporal lobes. Culture of the pus disclosed beta hemolytic streptococcus. The primary source was not discovered.

Comment: Another case of metastatic brain abscess with unknown primary source and a rapid downhill course best explained by herniation of the cerebellar tonsils following spinal fluid puncture.

Case 3

A child was admitted to St. John's Hospital, January 12, 1961, with a four-day history of nausea, vomiting, headaches, and lethargy. Admission diagnosis was that of gastroenteritis. The patient was afebrile with a white count of 8,500, 65% polymorphonuclears and 34% lymphocytes. Hemoglobin was 12.3; chemistry was negative, except for 2+ cephalin flocculation at 24 hours, and 4+ at 48 hours. The child was seen by a pediatrician January 17, 1961, with a tentative diagnosis of electrolyte imbalance and hepatitis. The temperature and white count remained normal. Spinal fluid examination performed January 17 disclosed one white cell protein of 77 mg. %, a sugar of 78 mg. %, and chlorides of 123. The patient was first seen in neurologic consultation on January 21, 1961; the examination disclosed a lethargic child who could be aroused, with ensuing hyperirritability. Pupils were active and equal, and ocular movements normal. There was crack-pot resonance on percussion of the skull, along with papilledema of the right eye. Mild neck rigidity was present.

Approximately 12 hours after neurologic consultation January 21, 1961, the child developed repeated focal seizures, involving the left arm and then the entire left side, and subsequently the seizures became generalized. Previous x-rays had disclosed a normal chest January 17, a small bowel ileus, and a normal skull on January 21. A right cerebral angiogram, performed shortly after the child went into repeated seizures, disclosed a marked shift of the anterior cerebral vessels across the midline to the left, indicating a large right frontal mass. A ventriculogram was also performed, disclosing a marked shift to the left, including the third ventricle. There was incomplete filling of the right frontal horn. Immediate craniotomy was performed after the child had become comatose, with widely dilated pupils, following the ventriculogram. Craniotomy encountered a large pus pocket; and the abscess, which was encapsulated, was excised. The child, however, never regained consciousness, remained decerebrate, and expired less than 12 hours after the diagnosis of a brain abscess had been established. Culture revealed nonhemolytic streptococcus. Autopsy was not granted.

Comment: The child was originally diagnosed as having

gastroenteritis with subsequent change of diagnosis to probable hepatitis; when he developed lethargy and papilledema, a diagnosis of a cerebral neoplasm was entertained. However, a craniotomy disclosed a large right frontal brain abscess. Unfortunately treatment was begun too late to be effective.

Case 4

A 33-year-old patient was first seen in neurologic consultation December 7, 1959, complaining of gait disturbance with a known history of onset of weakness in the left leg at age 29. Neurologic examination disclosed hyperreflexia with clonus of the left leg and positive toe signs on the left, as well as decreased superficial reflexes over the left abdomen and a mild increase in reflexes of the left arm. Cranial nerve examination and a Schillings test were negative. Hemoglobin was 13.7, with normal WBC. Spinal fluid protein was 44 mg. %; sugar was 70 mg. %; there were no cells and a normal gold curve. Spine x-rays and a complete myelogram, all the way to the foramen magnum, were negative. A diagnosis of a spinal form of multiple sclerosis was made.

The patient was admitted to St. John's Hospital February 17, 1961, after an episode of acute onset of weakness of the right arm and right-sided Jacksonian seizures, confined to the right arm with later spread to the right side of the face. Severe headaches without emesis were present. On admission his temperature was 99.2°, and on the following day, 101.4°; otherwise it was normal. On February 23, 1961, the patient progressed to a complete right hemiparesis. No papilledema was present. On February 20, 1961, a left cerebral angiogram suggested depression in the callosal vessels. A pneumoencephalogram February 21, 1961, disclosed the left lateral ventricle to be depressed and displaced slightly toward the right. Previous skull and chest x-rays were negative. Spinal fluid protein revealed 75 mg. % and no pleocytosis. On February 23, 1961, a left craniotomy was performed, and an abscess cavity was encountered in the left superior parietal area. Approximately 15 cc. of pus were removed, and culture of this material revealed nonhemolytic streptococcus. Subsequently the abscess was repeatedly drained and the patient was placed on oral antibiotics, including chloromycetin and streptomycetin. Though he recovered from the operation, he was left with a mild to moderate expressive aphasia and subsequent focal Jacksonian and grand-mal seizures, which were eventually controlled by anti-convulsants.

Comment: This case demonstrates successful cure of a brain abscess in an individual previously diagnosed as also having multiple sclerosis.

Case 5

This patient, age 23, known to have a congenital cardiac defect and a Klippel-Feil deformity, was admitted to Miller Hospital, December 3, 1964, with a fever of 103°, headache, emesis, and a stiff neck. Nine days prior to admission she had complained of nausea, diarrhea, and one fainting spell. Three days later she improved only to regress with subsequent malaise and listlessness. A week prior to admission a temperature of 101° had been noted. The night prior to admission she had developed an acute headache with stiffness of the back and neck and excessive sweating. When seen in consultation six hours after admission, her temperature was 102°, pulse 108, respiration 60. Obvious Klippel-Feil deformity was noted with an extremely short neck. There were cardiac enlargement with systolic and diastolic murmurs, strongly positive meningeal signs, vertical nystagmus, constricted visual fields, and no papilledema. Spinal puncture in the decubital position disclosed an opening pressure of 560 mm. of water. The spinal fluid was thick and turbid, containing 635,000 cells per cc., predominantly polymorphonuclear leukocytes. Protein was 860 mg. %, and no sugar was present in the spinal fluid. Sedimentation rate was 1, hemoglobin 14.4, white count 23,100 with 94% polymorphonuclear neutrophil leukocytes, and a later white count to 36,300.

The patient was treated with massive intravenous injection of penicillin and chloromycetin. The next morning she was confused and lethargic and developed disconjugate eye movements. The right pupil later became fixed, and the patient became decerebrate shortly prior to expiration on December 4, 1964, 28 hours after she was admitted to the hospital. At autopsy a brain abscess 5 cm. in largest diameter was found in the right occipital area with rupture into the ventricles and a secondary basilar meningitis. Marantic vegetations were found in the mitral valve. There was a cor triloculare with a single ventricle, without any transposition of the vessels, and a Klippel-Feil deformity. A spinal fluid and blood culture subsequently disclosed gamma streptococcus.

Comment: Case of a congenital heart deformity with marantic vegetations with secondary gamma streptococcus septicemia and a ruptured occipital brain abscess and purulent bacterial meningitis with expiration 28 hours after admission to the hospital.

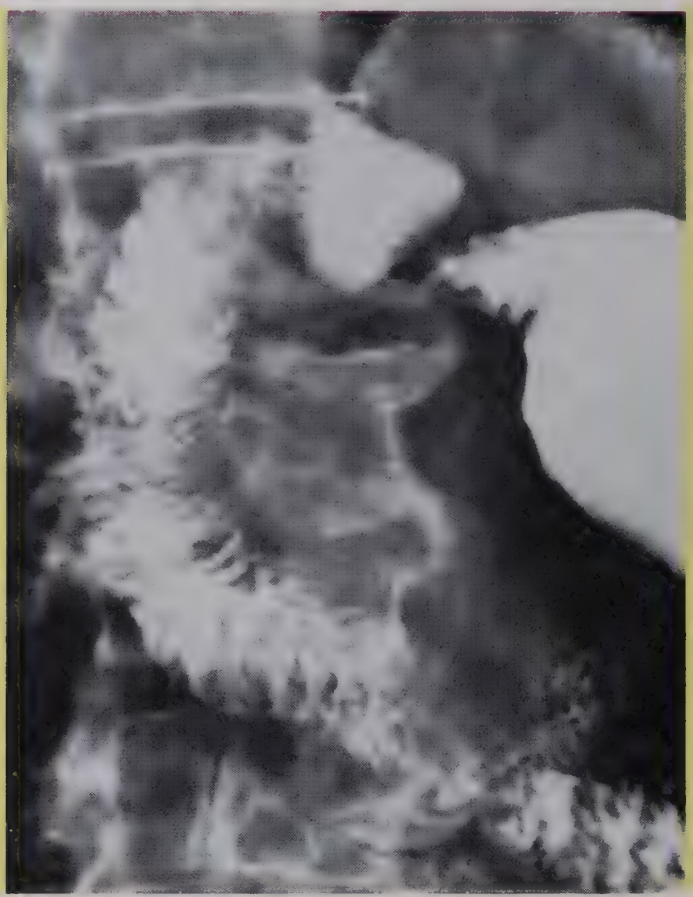
For Frontier Baldness

A man need not grow bald on the frontier. All he had to do was mix a quart of clean tar, a quart of whiskey and a quart of honey or molasses in a pewter dish and heat for twenty to thirty minutes without bringing the mess to a boil. He skimmed off the tar and bottled the brew, which was so potent that grannies claimed a tablespoon taken three, four, or five times a day as the stomach allowed, not only put hair on a man's head, but on a woman's chest. In case the problem was simply to grow a mustache, all a middle-border youth had to do was anoint his lip with sweet cream and have a black cat lick it off at midnight.*

*Richard Dunlop: Doctors of the American Frontier, 1965.

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.



One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

THE RESTLESS DUODENUM...

DUODENUM—(Conventional X-ray) The restless duodenum makes radiographic diagnosis difficult, uncertain and often unproductive. Is this duodenum normal?

Pro-Banthine®

brand of

propantheline bromide

For fifteen years Pro-Banthine has been the most widely used anticholinergic agent in disorders of gastrointestinal motility and gastric hypersecretion. More recently Pro-Banthine has reestablished its pharmacologic effectiveness in facilitating diagnostic procedures using intragastric fibroscopy and hypotonic roentgenography.

How the X-rays were taken

In the hypotonic duodenograph[1,2] reproduced above, the gastrointestinal tract was relaxed with Pro-Banthine. The duodenum was intubated. Pro-Banthine in a dose of 60 mg. intramuscularly was used to assure prompt aperistalsis, and double-contrast visualization was achieved with ordinary barium and air.

The same pharmacologic efficiency has proved of pronounced value in such conditions as: *peptic ulcer, pylorospasm, biliary dyskinesia, functional hypermotility and irritable colon.*

...AT REST

SAME DUODENUM—(Hypotonic X-ray) Pro-Banthine-induced duodenal calm permits full anatomic appraisal in the same patient. Duodenal normality is now evident.

calms the gastrointestinal tract

Contraindications: Glaucoma; severe cardiac disease.

Precautions: Since varying degrees of urinary hesitancy may occur in elderly males with prostatic hypertrophy, this should be watched for in such patients until they have gained some experience with the drug. Although never reported, theoretically a curare-like action may occur with possible loss of voluntary muscle control. Such patients should receive prompt and continuing artificial respiration until the drug effect has been exhausted.

Side Effects: The more common side effects, in order of incidence, are xerostomia, mydriasis, hesitancy of urination and gastric fullness.

Dosage: The maximal tolerated dosage is usually the most effective. For most *adult* patients this will be four to six 15-mg. tablets daily in divided doses. In severe conditions as many as two tablets four to six times daily may be required. Pro-Banthine (brand of propantheline bromide) is supplied as tablets of 15 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg. The parenteral dose should be adjusted to the patient's requirement and may be up to 30 mg. or more every six hours, intramuscularly or intravenously.

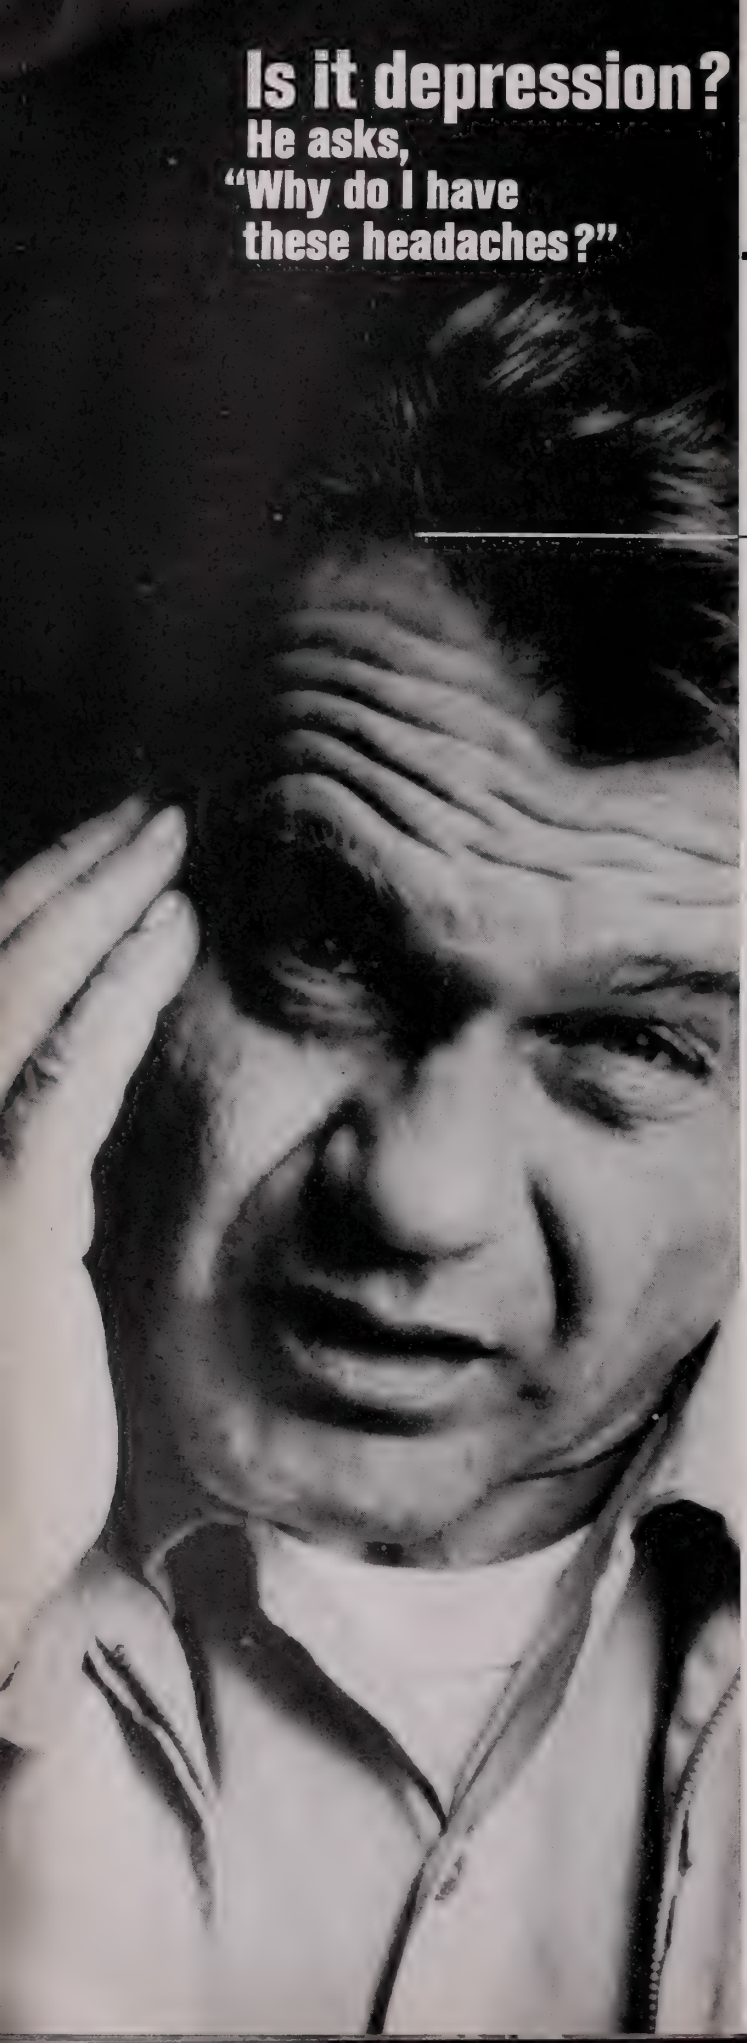
Case Finding in Cystic Fibrosis

In the January issue of Minnesota Medicine* is an article by Warwick and Koroshec describing mass screening techniques for cystic fibrosis and the results in Minnesota school children. These workers are to be commended on the prodigious effort expended in the testing of 20,071 children in 26 communities. The cooperation of the Mrs. Jaycees' organization and the school officials in this undertaking is an impressive example of the efforts of nonmedical personnel to work for the welfare of children.

Despite this great effort and the assistance of physicians in the community, no new cases were discovered in the tested group. However, three new cases were found among children who happened not to be in the tested group at the time.



Dr. Warwick was able to support his view that the incidence of cystic fibrosis is one per 1,000 births.

Dr. Warwick makes a plea at the conclusion of his article for the consideration of newborn nursery screening for cystic fibrosis with his device for performing a heat stimulus-chloride ion electrode sweat test. This instrument in Dr. Warwick's hands has proved an accurate diagnostic aid in the laboratory, but several considerations are worthy of second thought. Among the 20,071 children were found 1,500 who had elevated values in the test. On subsequent retesting with iontophoresis techniques, these 1,500 children proved to be normal. This leaves one somewhat perplexed as to the accuracy of the instrument, or the efficiency of its use, or perhaps the range of values considered to be normal.

To the suggestion that mass screening in newborns be carried out for cystic fibrosis one may draw a parallel to the legislation now in effect demanding testing of newborn infants for phenylketonuria. Many pediatricians feel that this legislation was hastily enacted and ill-advised when the controversy still rages over the efficacy of dietary measures for children with elevated levels of serum phenylalanine, the rarity of the disease itself in the general population (one per 20,000 births), the finding of some normal individuals with elevated levels of serum phenylalanine who have not been treated, and lastly the expense involved in such mandatory testing with low yields.

Lest anyone immediately accept the conclusion that mass screening techniques for cystic fibrosis in infants is desirable, let alone worthy of legislation, what facts should be

*Warwick, W. J., and Koroshec, JoAnn: Cystic Fibrosis Detection Clinic Program in Minnesota. Minnesota Med. 51:153, 1968.

...but his other symptoms:
functional somatic complaints, anxiety, insomnia, loss of interes anorexia, feelings of guilt
strongly suggest an underlying depression.

when the diagnosis is depression

ELAVIL® HCl
(AMITRIPTYLINE HCl | MSD)

Indications: Mental depression and mild anxiety accompany depression.

Contraindications: Glaucoma and predisposition to urinary ret tion. Not recommended in pregnancy.

Precautions and Side Effects: Drowsiness may occur within first few days of therapy. Patients should be warned against d ing a car or operating machinery or appliances requiring al attention. When depression is accompanied by anxiety or ag tion too severe to be controlled by ELAVIL HCl alone, a phenoth zine tranquilizer may be given concomitantly. Suicide is alway possibility in mental depression and may remain until signific remission occurs. Supervise patients closely in case they n require hospitalization or concomitant electroshock thera Untoward reactions have been reported after the combined u of antidepressant agents having varying modes of activity. cordingly, consider possibility of potentiation in combined use antidepressants. Monoamine oxidase inhibitor drugs may pot tiate other drugs and such potentiation may even cause dea permit at least two weeks to elapse between administration of t agents; in such patients, initiate therapy with ELAVIL HCl c tiously with gradual increase in dosage required to obtain satisfactory response. Caution patients about errors of judgm due to change in mood, and that the response to alcohol m be potentiated. May provoke mania or hypomania in man depressive patients.

Side effects include drowsiness; dizziness; nausea; exciteme hypotension; fine tremor; jitteriness; weakness; headache; hea burn; anorexia; increased perspiration; incoordination; allerg type reactions manifested by skin rash, swelling of face a tongue, itching; numbness and tingling of limbs, including perip eral neuropathy; activation of schizophrenia which may requ phenothiazine tranquilizer therapy; epileptiform seizures chronic schizophrenics; temporary confusion, disturbed conce tration or, rarely, transient visual hallucinations on high dos evidence of anticholinergic activity, such as tachycardia, dryne of the mouth, blurring of vision, urinary retention, constipatic paralytic ileus; jaundice; agranulocytosis.

Careful observation of all patients is recommended. The an depressant activity may be evident within 3 or 4 days or may ta as long as 30 days to develop adequately, and lack of respon sometimes occurs. Response to medication will vary according severity as well as type of depression present. Elderly patier and adolescents can often be managed on lower dosage leve

Supplied: Tablets containing 10 mg., 25 mg., and 50 mg. amitri tyline HCl, bottles of 100 and 1000; for intramuscular use, 10-cc. vials containing per cc.: 10 mg. amitriptyline HCl, 44 m dextrose, and methylparaben 1.5 mg. and propylparaben 0.2 m added as preservatives.

WHERE TODAY'S THEORY IS TOMORROW'S THERAP

considered? Cystic fibrosis is a serious but treatable disease. It occurs in varying degrees, the most serious variety causing death in early infancy. Dr. Warwick cites a figure of 36% as representing the mortality rate in cystic fibrotics during the first year of life. The least serious variety of cystic fibrosis causes varying degrees of disability from pulmonary disease in adults. One raises the question then: Is the disease diagnosable in the newborn without such obvious signs as meconium ileus? Since the disease is so serious in the tiny infant, how amenable to treatment is it? While answers to these questions are being pondered, perhaps it would be advisable to consider the present status of therapy in older children and adults.

Shwachman and associates[1] reported a series of 65 patients with cystic fibrosis who were over 17 years of age (mean 20½ years). Fifty-five were in what they termed "excellent" to "mild" clinical status, the other 10 being in "moderate" health. Follow-up care was good in most. In 34 the diagnosis was made before the age of 10 years. The authors state that the major factor in the maintenance of a good clinical state was the use of tetracycline in the treatment of pulmonary disease to keep the bronchopulmonary tree "clean." Additional credit must be afforded dietary therapy and pancreatic enzyme replacement.

Doershuk and co-workers[2] have evaluated the use of a comprehensive therapeutic program of hospital and home care with mist tent treatment, intermittent aerosol therapy, and segmental postural drainage plus antibiotic treatment. This regimen they judge to be effective in the arrest of the usual progression of pulmonary disease in cystic fibrosis. It would appear that the next step would be an evaluation of a prophylactic program on a random selection basis to determine whether the therapeutic program in patients with no pulmonary involvement would effectively prevent or offset the progressive pulmonary disease. However, the danger of promoting unjustifiable invalidism in children with diagnosed cystic fibrosis but without pulmonary disease would be a most cogent consideration.

Thus one concludes that both early diagnosis and careful and thorough medical follow-up materially affect morbidity and the prognosis for longevity in cystic fibrosis. But can this be further improved by infant screening techniques? Some doubt exists that the newborn can prove to be a satisfactory subject for screening tests in the light of providing adequate sweat samples. Additional considerations are the cost of the equipment and the training of nursery personnel in its proper use, particularly when the yield is apt to be so low.

It would seem more rational that the general practitioner and the pediatrician be continually alerted to the possibility of cystic fibrosis in any child who fails to thrive or who manifests pulmonary symptoms either of persistent or recurrent nature. It has been the policy of my colleagues and myself to carry out sweat tests on any child with symptoms of an asthmatic nature. We would agree that the younger the child the more pernicious the character of cystic fibrosis is likely to be and, consequently, the less amenable it is to therapy.

With the aforementioned reservations in mind we nevertheless await the efforts and the results of a pilot study by Dr. Warwick and co-workers in carrying out such testing in a large series of newborn infants. Those caring for children might be less in doubt regarding the wisdom of such a program if these workers can provide documentation for their thesis that mass screening for cystic fibrosis in newborns is practicable, accurate, and beneficial in reducing mortality from the disease.

DOW

Early Invasive Carcinoma of the Cervix*

A LARGE PART of the recognition of early cervical cancer has been the result of the ever wider application of the vaginal smear. This has raised some problems; but an infinitely greater good has resulted. For the first time there is a vision of the possibility of practically excluding deaths from a major cancer.

Some of the problems of the smear itself, its interpretation and handling, were discussed before this society last year. This discussion included the indications and techniques for the application of conization of the cervix. In this procedure the potentially cancerous surface of the endocervix and of at least a further centimeter in all directions of the surface of the vaginal portion of the cervix is removed for microscopic examination. A detailed diagnosis and the type of treatment to be applied should come from careful evaluation of this. Such conization is indicated only when no gross lesion is available for biopsy.

The interpretation of the findings in terms of the indications for specific types of treatment has been the source of much study and argument. The concept that a cancer which is apparently superficial may be safely treated either by conization alone as described above or by simple removal of the uterus has been widely accepted. That the former represents a much too dangerous gamble seems clearly established. Simple removal of the uterus apparently offers a much greater chance of permanent cure of an apparently superficial cancer. It has been established without question, however, that the cure rate is not complete. This raises questions as to the desirability and effectiveness of more radical treatment and the circumstances under which it might be justified.

The Department of Obstetrics and Gynecology at the University of Minnesota has been attempting to obtain information which may be applicable to such decisions. There is a relatively inactive form of the cervical cancer which can be recognized by examination with the microscope. It is unlikely that such cancers have spread beyond the surface, and they are being treated by simple removal of the uterus. When the cancer is made up of actively reproducing cells in masses on the surface or into glands; when there is a question as to whether microscopic invasion of the underlying tissue has occurred, or when the cancer extends to the cut margin of the cervical cone and so is in an unknown superficial or invasive state in the remaining tissue, either more radical forms of surgery or irradiation with x-ray and cobalt^{60} and radium have been used in the hope of increasing the cure rates. The effectiveness of these is also not yet established, but information is being collected. Various types of radical surgery are being tested.

Suicide*

THE RIGHT "to be or not to be," isn't that the question? Each man destroys himself in his own unique way, albeit time factors and methods of accomplishment vary. Besides outright self-destruction, we have many formes frustes† of suicide, as seen in alcoholism, addiction, self-mutilation, malingering, accident-proneness, polysurgery, and even smoking. All interest us, all involve us, all concern us, all violate us. It is fruitless to think we can deny man's right, choice, or need to destroy himself. Our basic obligation as physicians is to offer the patient time for reflective reconsideration under different circumstances. This is our responsibility to our fellow man, and no more.

†See Test Your Word Score Page 1213.

To help you manage patients with circulatory disorders:

Initiate therapy with **Hydromox*** Quinethazone 100 mg. (two 50 mg. tablets) daily for 15 days

Many patients with circulatory disorders (essential and benign hypertension, congestive heart failure) may obtain the greatest benefit from HYDROMOX Quinethazone when it is given in a single daily a.m. dose of 100 mg. (two 50 mg. tablets). This dosage usually relieves edema by effective diuresis, and reduces diastolic and systolic pressure. We suggest continuing clinical evaluation over a 15-day period of therapy. If results are satisfactory, a reduction to 50 mg. (1 tablet) daily will usually be adequate for maintenance.

Precautions: Electrolyte abnormalities may be aggravated or produced. Caution is important during prolonged or intensive therapy and when salt intake is restricted. Hypokalemia has been mild and infrequent, and other electrolyte abnormalities rare. The possibility of potassium depletion and its toxic sequelae must be kept in mind, particularly in cirrhotics and patients receiving digitalis. As a preventive measure the use of foods rich in potassium, such as orange juice, may be desirable. Although not a thiazide, HYDROMOX may possess certain characteristics of the thiazides. They have been known to cause jaundice with liver involvement and pancreatitis; hematological complications such as purpura with or without thrombocytopenia and leukopenia (neutropenia); increases of serum uric acid; decreased glucose tolerance as evidenced by hyperglycemia and glycosuria thus aggravating or provoking diabetes mellitus and azotemia in patients with renal disease; photoallergy. Discontinue use a few days prior to elective surgery. When added to a regimen that includes ganglionic-blocking agents, the dosage of these latter preparations should be reduced. Also reduce dosage when one or more of these antihypertensive agents is added to an established HYDROMOX regimen. Contraindicated in anuria. Observe for possible hematologic complications.
Side Effects: Skin rash; gastrointestinal disturbances (chiefly nausea), weakness, dizziness. These seldom require cessation of therapy, and can be relieved by reducing dosage or correcting electrolyte imbalance.
Warning: Enteric coated potassium tablets have been implicated in small bowel lesions and should be used only when adequate dietary supplementation is not practical.

Irregular Blood Group Antibodies

In an Eastern newspaper in an editorial entitled "Human Blood Giveth or Taketh Away," the writer called attention to the untimely death of a 30-year-old married woman, following an emergency appendectomy and a single blood transfusion. The article pointed out that this tragedy was not due to lack of surgical skill but rather to a major blood-group incompatibility, despite the fact that both donor and recipient were group O, Rh positive. The woman's blood contained so-called irregular antibodies incompatible with the donor's cells.

With increasing knowledge of blood-group systems, it truthfully can be said that every time a person is transfused he is exposed to some antigenic factor or factors which his body will identify as foreign and to which it may build up antibodies. To the surgically oriented specialist, the problem of irregular blood-group antibodies has become of increasing interest.

We might ask ourselves three questions:

What Are These Irregular Antibodies?

We are all familiar with the naturally occurring antibodies (anti-A and anti-B) in blood serum, for they form the basis of all blood typing. To acquire unnatural or, to use a more exact term, "irregular antibodies," we must have foreign particles or antigens introduced into our hematologic system. Our rejection mechanism protects against such intrusion by the development of irregular antibodies. Serologists are familiar with more than 100 such antigens which, if introduced, are capable of provoking such an antibody response. Once the response has been initiated, these antibodies remain forever lurking within the serum.

Fortunately, a large number of these known antigens have very limited potential for antibody formation, and their ability to stimulate antibody production depends on their incidence in the population, the amount of antigen introduced, and the individual's capability of antigenic response. Once the response has been evoked and the antibodies produced, their capability of destroying subsequent cells carrying such antigens is great, and blood-group incompatibilities exist. The subsequent finding of compatible blood donors whose erythrocytes lack the corresponding antigen may then become extremely difficult when time is short and additional transfusions become necessary.

How Are These Antigens Introduced?

There are but two avenues: transfusions and pregnancy. Almost every Rh-negative woman will have introduced into her circulation during pregnancy fetal cells which, if carrying the Rh as well as other antigens, will be capable of initiating this antigenic response. Fortunately such a reaction will also be influenced by her blood type, for if her blood is incompatible with her infant's blood, that is, if an Rh-negative woman has anti-A or anti-B antibodies in her plasma, it is unlikely that anti-Rh antibodies will be initiated by the Rh-positive cells of a group A or a group B infant. Transfusion recipients do not fare so well. In 1966 there were 6,000,000 blood transfusions administered within the United States, with a mortality rate equal to that of appendicitis. Incidentally, there were, in addition to hemolytic deaths, deaths due to hepatitis acquired from transfusion. The danger as well as the therapeutic value of transfusions must be constantly emphasized. In addition, each transfusion inadvertently introduces many known antigens which are likely to cause an antigenic response.

Can Irregular Antibody Formation Be Avoided?

Because of the great morbidity and mortality associated with hemolytic disease of the newborn, much has been learned about the Rh factor and its antibodies. Some of this knowledge may be adaptable to other fields of medicine in the future. Today, all Rh-negative individuals receive Rh-negative blood, leaving pregnancy the remaining stimulant to the development of Rh antibodies. Approximately 13% of Rh-negative women are mar-

ried to Rh-positive men, but since to the three admonitions of the marriage covenant (love, honor, and obey) we cannot add a fourth (be Rh negative), little more can be done to further reduce the overall perinatal mortality of eight to 10%.

Two factors have recently influenced the approach to eradication of this one irregular antibody. The first has been the demonstration of the repeated ability of fetal cells to penetrate the placental barrier, thereby entering the hostile environment of the maternal serum and stimulating antibody production. Fetal cells can be demonstrated by elution methods during almost every pregnancy, the greatest shower coming with the delivery itself. The second factor is the knowledge that when an excess amount of antibody is presented coincidently with a corresponding antigen, no active immunity develops: that is, passive immunity protects against active immunity.

Thus, if an Rh-negative woman who has an Rh-positive fetus with a blood group compatible with hers is given high-titer anti-Rh gamma-globulin immediately after delivery and before active immunity has developed, she will remain immune and never develop irregular antibodies for the Rh factor. Obviously, this same precaution will have to be repeated with each pregnancy. In some 1,000 pregnancies protected in this manner, not a single irregular antibody has developed. This may be the first step in solving other rejective mechanisms, such as those encountered in unsuccessful organ transplants.

Unfortunately, no such approach has as yet been demonstrated for protection against other antigens inadvertently introduced either during pregnancy or with transfusions. Until such hazards are eliminated, we must agree with the Eastern editorial writer in saying, "blood giveth or taketh away," and should add parenthetically, "it is many times more noble to give than to receive."

Postural Vertigo

SELDOM DOES a day pass in which the general physician or otologist does not see a patient who complains of postural vertigo. The features of the condition have been succinctly presented by Dr. Lindsay.* He points out that a few well-directed questions will usually identify this type of vertigo and that the production of positional nystagmus by postural testing gives objective proof of the disorder.

For an exhaustive treatise on the subject the reader is referred to the work of Barber.[1]

Neuro-otologic investigation including routine postural tests, caloric vestibular tests, and both pure-tone and speech audiometric examinations should be done in all cases of postural vertigo. In the cases with findings which do not suggest a need for more extensive examination to rule out specific central nervous system disease or labyrinthine disorder, a diagnosis of benign paroxysmal vertigo is made. These patients are informed that their condition is not serious and that it can be expected to subside in a few months. The postural vertigo may never return but in many cases a similar episode, lasting a few months, may occur in the future. Some patients, unfortunately, continue to have postural vertigo indefinitely.

A useful drug is a combination of nicotinic acid, 50 mg, and meclizine hydrochloride, 12.5 mg, taken four times daily for three months. If the symptoms are still present after this, the drug is continued indefinitely. Follow-up examination in four to six months, including audiometric and caloric vestibular tests, should be done in every case to avoid the possibility of overlooking progressive disease.

No injection after all!

This penicillin produces high, fast levels—orally.

Pen•Vee® K is usually so rapidly and completely absorbed that therapeutic penicillin levels are attained within 15 to 30 minutes. Thus it can often obviate the need for penicillin injections. The higher serum levels produced generally last longer than with those of oral penicillin G.

Indications: Infections susceptible to oral penicillin G: prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.
Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.
Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.
Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.
Adverse Reactions: (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").
Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

Intrauterine Fetal Transfusion for Severe Erythroblastosis*

THE NUMBER of cases of erythroblastosis severe enough to require treatment of the fetus before birth is very small. Babies affected by any degree of Rh disease are relatively uncommon, occurring only about once in 120 pregnancies. Some are so mildly affected that they require observation only, but no active treatment. Most of the others can be successfully treated by exchange transfusion of blood after birth at full term. Because some are so severely affected that they would die in utero before the end of the pregnancy, labor sometimes has to be induced prematurely in order to prevent further deterioration and to permit treatment by exchange transfusions.

However, in about 8% of these affected pregnancies, or about one in 1500 of all pregnancies, the fetus can be expected to die before 32 weeks' gestation, eight weeks before term. We do not dare to induce labor earlier than this because of the combined risks of prematurity and erythroblastosis. This is a problem which arises infrequently, but to the woman involved it is a very serious one indeed. In most cases she has already lost several pregnancies and therefore realizes that she has practically no hope of ever having a live baby.

The outlook for such patients has been changed since late in 1963 when a method was devised for treating these otherwise hopelessly affected fetuses by blood transfusions before birth. The aim of this procedure is to try to keep the fetus alive until such a stage of pregnancy is reached at which the risk of prematurity is no longer excessive.

The procedure is carried out in the x-ray department of a hospital. Although the mother is given fairly heavy sedation to keep her and her fetus quiet, she is not given a general anesthetic for the procedure. After localizing the fetus as accurately as possible, a local anesthetic is injected into a small area of the mother's abdomen. A large needle is inserted through this anesthetized area into her uterus and, hopefully, into the abdomen of the fetus. A pliable plastic tube is passed down the bore of the needle and the needle withdrawn quickly so that the fetus will not injure itself if it moves. Further x-rays are taken to make sure that the tube is in the right position, namely, in the abdominal cavity of the fetus. Red blood cells from an Rh negative donor which will not be affected by the Rh disease are then injected through the tube. The mother is kept quiet in hospital for at least 48 hours to reduce any possible tendency for her to go into labor because of the irritation of the uterus. The procedure may have to be repeated several times until the fetus is mature enough to permit premature delivery and extrauterine treatment by exchange transfusions.

Since January, 1964, more than 130 intrauterine fetal transfusions have been given to more than 63 fetuses in Winnipeg, Canada. Twenty-six of these are alive today. Although it was frequently difficult to make a definite diagnosis of the cause of death in the cases which were lost, we think that most of them died because of the severity of their disease when fetal transfusion was first attempted. We estimate that the operative mortality, i.e., the risk of a fetus dying as a result of a transfusion, is about 15%. However, in the past 18 months our operative mortality has been only about 7%, probably due to the increased experience and improved skill. Obviously, in such complicated maternity cases, there are also risks to the mother.

Intrauterine fetal transfusion offers at least some hope to any woman no matter how bad her past obstetric experience or how strong her Rh antibodies are. Because of the obvious risks and difficulties involved, the procedure should be carried out only in well-equipped centers prepared to deal with all possible complications. Even in such centers under the best possible circumstances the operation is very far from the ideal answer to this problem. Recent developments give rise to hope that it will soon be possible to prevent Rh negative women from developing antibodies at all. If this materializes, most of our present methods of treatment, including exchange transfusions and intrauterine fetal transfusions, will become obsolete.

Letter to the Editor

Professor Lenggenhager and Dr. Stirnemann send you their very best greetings, and we all want to thank you again most sincerely for the opportunity which you have offered us to show our American colleagues what is going on in medicine here in Berne. The Department of Education was also very happy about the Berne issue of your Journal and look forward to their 100 copies. The rising number of students pose great problems in this country with respect to financing the universities and the Berne issue will give them a splendid opportunity to show some returns on their investments—so you have really done medicine here in Berne a great service for which we owe you our sincere gratitude.

P. Lundsgaard-Hansen, M.D.
University of Berne, Switzerland

EDITOR'S NOTE: The University of Berne, Switzerland, Issue of MINNESOTA MEDICINE will appear in December or January. Your Editor and Professor Lenggenhager were fellow students under Professor de Quervain a number of years ago.

...can you depend on less?

For profound calming effect in moderate to severe mental and emotional disturbances of everyday practice.

Before prescribing, see complete information, including adverse effects reported with phenothiazines and symptoms and treatment of overdosage, in SK&F literature or *PDR*. The following is a brief precautionary statement.

Contraindications: Comatose states or the presence of large amounts of C.N.S. depressants.

Precautions: Potentiation of C.N.S. depressants may occur (reduce dosage of such agents when used concomitantly). Use with caution in patients with chronic respiratory disorders. Antiemetic effect may mask overdosage of toxic drugs or obscure other conditions. Administer in pregnancy only when necessary. Because of possible drowsiness use cautiously and warn patients who operate vehicles or machinery.

Adverse Reactions: Drowsiness; dry mouth; nasal congestion; constipation; amenorrhea; miosis; mild fever; weight gain; hypotensive effects, sometimes severe with I.M. administration; epinephrine effects may be reversed; dermatological reactions; parkinsonism-like symptoms on high dosages (in rare instances, may persist); lactation and moderate breast engorgement (in females on high dosages); and less frequently, cholestatic jaundice (use cautiously in patients with liver disease). Adverse reactions occurring rarely, include: mydriasis; agranulocytosis; skin pigmentation; epithelial keratopathy; lenticular and corneal deposits (after prolonged substantial doses).

Available: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg.; Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg.; Injection, 25 mg./cc.; Syrup, 10 mg./5 cc.; Suppositories, 25 mg. and 100 mg.

The Editor's Soliloquy

Health Maintenance—Ridiculously Simple

The best medicine on earth is that which provides continuous good health. Such medical care can be had! And free at that! To have and to hold optimum health is so simple that it seems almost too elementary to discuss; yet, paradoxically, to attain ideal physical and emotional well-being is so phenomenal an achievement that only a few rare individuals can demonstrate the self-discipline required to maintain "a sound mind in a sound body."

If those hypochondriacs who complain of aches and pains, fatigue and malaise, worries and apprehensions, would accept the doctor's sound advice, when he wisely declines to supplement it with a needless operation or a written prescription, they would require no tranquilizers for "nerves," no analgesics for "headaches," no antacids for "burping and heartburn," no colagogs for "dyspepsia," no laxatives for "temperamental bowels," no emulsions for an "irritable colon," and no hypnotics for "insomnia." No surgery or medication whatsoever is necessary for those innumerable spectral disorders men and women subconsciously devise to parry the petty problems and crises of life.

It is these residual traces of inadequacy, inferiority, conflict, aggression, and hostility that generate hypochondriasis in the emotionally frustrated, the maritally dissatisfied, the socially maladjusted, the economically disgruntled, whose numerous maladies, eternal fatigue, overweight and lack of physical trim are not signs of organic disease but symptoms of unsuccessful compromise with the facts of life. They comprise the spectrum of imaginary morbidities for which there can be no specific medical cure and no operative relief; and they afflict chiefly the middle-aged, who fill the doctors' offices in the fond hope that the physician can do for them what they are failing to do for themselves.

Their persistence in seeking medical aid would be heroic, if they were Galahads in search of the Holy Grail! In their quest for palliation they become gullible prospects for the advertisers' slick blurbs and the cultists' fraudulent claims, a vast and lucrative field of exploitation which the conscientious and honorable physician declines to enter.

In contrast to these neurotically afflicted middle-aged folks the younger generation, whatever their frailties and deficiencies appear to be comparatively immune to the countless functional disorders so common to their elders. But the physician who tactfully recommends to his patient that she restore her body and mind to the robust physical and emotional integrity of youth is met with the impenetrable resistance and recalcitrance of a thousand and one excuses—excuses and more excuses! She won't forfeit her alibi! She wants the magic elixir! She cannot accept the fact that the preventive maintenance of physical trim and good health and a return to the fresh glow and resiliency of youth is the simplest therapy for the prevention and elimination of a host of functional maladies which she has construed as organic disease.

It does require superlative self-discipline and that is the difficulty.

Brief summary. Blurring of vision, dry mouth, difficult urination, and flushing or dryness of the skin may occur on higher dosage levels, rarely on usual dosage. Administer with caution to patients with incipient glaucoma or urinary bladder neck obstruction. Contraindicated in acute glaucoma, advanced renal or hepatic disease or a hypersensitivity to any of the ingredients.

A. H. ROBINS COMPANY, RICHMOND, VIRGINIA 23220

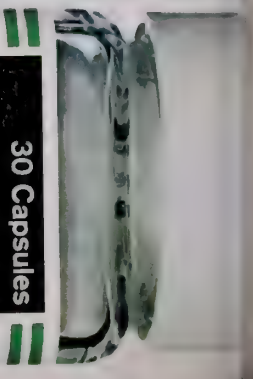
A·H·ROBINS

TWO WAYS TO GIVE YOUR PATIENTS A MONTH'S SUPPLY OF THERAPEUTIC VITAMIN C:

45 CABBAGES OR 30 ALLBEE WITH C

Your patient would have to eat 45 cabbages a month (1-1/2 a day) to get as much vitamin C as is contained in just one bottle of 30 Allbee with C capsules (taken one capsule daily). In addition, each capsule provides full therapeutic amounts of the B-complex vitamins. For example, as much niacin as 2 pounds of sirloin steak.

Write "30" for B and C deficiencies. This handy bottle of 30 Allbee with C capsules gives your patient a month's supply at a very reasonable cost. Also the economy size of 100. Available at pharmacies on your prescription or recommendation.



A. H. Robins Company, Richmond, Va. 23220.

30 Capsules
Allbee® with C

Each capsule Contains:

Thiamine mononitrate (Vit. B_1)	15 mg
Riboflavin (Vit. B_2)	10 mg
Pyridoxine hydrochloride (Vit. B_6)	5 mg
Niacinamide	50 mg
Calcium pantothenate	10 mg
Ascorbic acid (Vit. C)	300 mg

Acute Viral Encephalitis and Post-Infectious Encephalomyelitis

Emergency Therapy*

MICHAEL E. BLAW, M.D.†
Dallas, Texas

THIS REPORT IS primarily concerned with the treatment of acute viral encephalitis and acute post-infectious encephalomyelitis; however, it should be emphasized that the differential diagnosis is often quite broad. Of particular concern, especially in children, is the specter of exposure to exogenous toxins. In the final analysis the immediate diagnosis and subsequent appropriate emergency therapy depends upon critical appraisal of the history and physical examination.

Since for the most part specific chemotherapy for both viral encephalitis and post-infectious encephalomyelitis is not available, discussion of treatment will necessarily be centered about supportive care and complications. Although the pathological hallmark of viral encephalitis is one of diffuse inflammation of the nervous system, whereas post-infectious encephalomyelitis is characterized by symptoms consequent to disseminated perivenular demyelination, in many respects treatment overlaps. In the discussion to follow, therapy for both processes will be presented in common, recognizing that the application to any given patient depends on the severity and extent of these exceedingly variable pathological processes.

Supportive Treatment

Eliminate Stimuli

Early in the clinical course, particularly with encephalitis, the patient may be hyperexcitable, reacting violently even to the most innocuous environmental stimulation. As a consequence, a room should be chosen which is as far removed from the hubbub of the ward as possible. The blinds should be drawn and the room maintained in subdued light. Barbiturates may be required to sedate the severely agitated patients. Special nurses are indicated until the clinical course stabilizes.

*Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.

†Professor of Pediatrics and Neurology, Division of Neurology, Children's Hospital, Southwestern Medical School, Dallas, Texas.

Minimize Fluid Intake

Although on admission the patient may have only minimal symptoms, progression can be very rapid. In the acutely hospitalized it is probably judicious to withhold oral feedings and initiate intravenous fluids until a clear picture of the patient's clinical course is obtained. Cerebral edema may play an important role in both mortality and residual morbidity, particularly in viral encephalitis; therefore, intravenous fluids should not exceed maintenance. Once the patient has stabilized, tube feeding, soft bland diets or regular diets can be initiated as circumstances dictate.

Airway

An unobstructed airway is better therapy than an oxygen tent. Pharyngeal suction should be used liberally. If an adequate airway cannot be maintained, tracheostomy is indicated. Mechanical supports for respiration may be required. Urinary retention occurs quite commonly, requiring catheterization.

Cooling

The presence of fever increases metabolic demands and may contribute to the associated cerebral edema. The patient's clothing should be removed and the temperature of the room lowered to approximately 65°. If air conditioning is not available, fans should be used to provide adequate circulation of air. Salicylates may be employed when practical. A cooling blanket can be used when the above means fail, but shivering may reduce the benefit derived therefrom. However, phenothiazines can be used to control shivering, but care must be taken not to produce hypotension.

Treatment of Complications

Convulsions

Convulsions, both generalized and focal, often occur during the clinical course of both diseases. When present they complicate nursing care, potentiate the associated cerebral edema, and increase the likelihood of secondary problems such as aspiration pneumonia. Phenobarbital and dilantin may be used for seizure control, but care must be taken in titrating the anticonvulsants against the seizure activity so that excessive central nervous system depression does not occur. If hepatic disease is present, phenobarbital should be given in preference to dilantin. The latter requires the liver for detoxification. In the presence of complicating renal disease, dilantin should be employed, since phenobarbital for the most part requires normal renal function for excretion.

Cerebral Edema

Cerebral edema and its attendant increased intracranial pressure are prime determinants in the ultimate prognosis; treatment of this will be dealt with in another part of the symposium. However, it should be noted that steroids, although beneficial in reducing the increased intracranial pressure associated with tumors, may not be effective in the edema associated with viral encephalitis. Of the hyperosmotic agents currently in use, glycerol has some obvious advantages[1] as it can be given by mouth and is rapidly metabolized. Toxicity is minimal and there is less tendency for rebound edema. Glycerol is given in an initial dose of 2 gm/kg with 0.5 gm/kg every four hours. A 50% solution in 0.9% saline is used. In the conscious patient, lemon juice can be added to ameliorate the sweet taste.

Antidiuretic Hormone

The syndrome of inappropriate antidiuretic hormone secretion occurs under a variety of circumstances, including certain malignancies, pulmonary disease, surgical anesthesia and a number of neurological diseases such as viral encephalitis.[2] The syndrome is defined by (1) the presence of decreased serum sodium concentrations and serum osmolarity, (2) continued sodium excretion with relatively increased urine osmolarity, and (3) no evidence of fluid volume depletion or abnormal renal or adrenal function. In the presence of inappropriate anti-diuretic hormone secretion, even maintenance levels of intravenous fluids can lead to progressive water intoxication. Fluid restriction below maintenance levels (500-700/m^2) is indicated. Inappropriate anti-diuretic hormone secretion occurring during acute viral encephalitis is usually transient.

Steroid Therapy

Both basic virological and clinical studies suggest that steroids are not effective and indeed may well be contraindicated in acute viral

encephalitis.[3,4] However, considerable literature has developed relating to the use of steroids in post-infectious encephalomyelitis. The initial reports were most encouraging. More recently, controlled studies, both retrospective[4,5] and prospective,[6] have indicated that steroids do not alter either the mortality or morbidity of post-infectious encephalomyelitis.

The Future of Viral Chemotherapy

In the dawn of knowledge related to viral infection it was hoped that eventually a single anti-viral agent could be developed which would serve as a universal antidote but in the light of present day information it has become increasingly apparent that such a therapeutic agent is not likely to be forthcoming. This is a consequence of the fact that each virus is a distinct entity with its own unique structure and the capacity to induce in the host cell enzymes particular to itself. Nevertheless, the search for effective agents is ongoing.[7] Three such anti-viral agents have attracted considerable attention.

Host-Cell Specificity

Interferons are basic polypeptides induced in the host cell by viral particles. Although interferons lack viral specificity, there appears to be strong but not absolute host-cell specificity. This and the fact that they appear to be effective only within the first few hours of an infection limit their clinical utility.

Prevention

Adamantadine (Symmetrel) is an agent which prevents the penetration of the virus into the host cell; but, because it does not affect the virus after penetration, its use is most likely to be in prevention rather than cure.

Antimetabolite

Idoxuridine is an anti-metabolite effective against some deoxyribonucleic acid viruses. Clinically it has been very effective when applied topically in patients with keratoconjunctivitis due to herpes simplex. It has also been employed systemically in a few patients with herpes simplex encephalitis.[8] These initial case reports are indeed encouraging.

Whether or not idoxuridine proves effective in herpes simplex encephalitis, it is apparent that anti-viral agents will be developed that are specifically tailored to individual viruses. Unless there is parallel development of laboratory procedures allowing for specific viral diagnosis early in the course of the disease, we may find ourselves in a position of having at our fingertips a variety of therapeutic agents but handcuffed by our inability to select the proper drug.

Major Motor Seizures*

FERNANDO TORRES, M.D.†
Minneapolis, Minnesota

Most texts and monographs dealing with epilepsy start with a reference to historical reports of epileptic attacks and their implications according to the time and type of culture involved. For many centuries the only form of convulsive disorder recognized as epilepsy was the major motor seizure, and its description used in ancient times is still valid.

Major Motor Seizures

A major motor seizure frequently starts with a cry, produced by the violent expiration associated with contraction of thoracic and diaphragmatic muscles. The subject may lose consciousness at the onset. Tonic and clonic convulsions follow, but either phase may be absent. There is foam at the mouth, and there may be incontinence of urine and sometimes also of feces. At the end of the convulsion there is a more or less prolonged period of apnea, terminated by a long inspiration. In most instances, the patient starts moving and talking a few minutes later. There is, however, a period of confusion of variable duration, during which there is only incomplete recovery of consciousness.

Because of the different mechanisms involved and the implications for prognosis and treatment, it is advisable to restrict the term "grand-mal" to major motor seizures which are generalized from the onset.

Focal Seizures

Any focal seizure may become a generalized convulsion, but it is important to distinguish between motor primary and secondary generalized seizures. The former is not preceded by aura because it is generalized from its onset; the latter may or may not be preceded by a warning. The aura is absent when the focal discharge spreads rapidly and consciousness is affected very early in the sequence of events.

Differentiation

Clinically it may be difficult to distinguish be-

* Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.

† Professor of Neurology, University of Minnesota Medical School.

tween major motor and focal seizures even after careful questioning of the patient and the relatives, especially in cases of rapidly spreading focal seizures. It is important to inquire not only about aura, but also about any postictal symptoms that may give a clue as to the focal nature of the seizure. The electroencephalogram is frequently helpful in questionable cases. In effect, the individual who suffers from grand-mal seizures will have a normal or only mildly abnormal electroencephalogram during interictal periods and, in the rare cases when a seizure can be electrically recorded, it is possible to see its generalized onset. On the other hand, patients whose convulsions start focally will usually have a significantly abnormal interictal electroencephalogram, and frequently one or more foci of abnormality may be detected.

Propagation

Propagation is a crucial factor in seizure mechanisms, since clinical manifestations may be absent or may become increasingly important according to the capacity of spread of an irritative activity. The initially focal epileptic phenomenon may spread in three ways: (1) following long fiber paths within the hemisphere; (2) projecting to homologous areas of the opposite hemisphere via the corpus callosum or the anterior commissure; (3) propagating along corticothalamic pathways and from the midline structures back to the cortex, bilaterally, and down the descending fiber tracts.

Generalized Seizures

Generalized seizures from the onset have been called "centrencephalic." This term comprises "grand-mal," "petit-mal" and "myoclonic-akinetic" attacks and was introduced by Penfield,[1] based on a theory according to which a centrally placed structure or set of structures around the brain stem and thalamic reticular systems is responsible for the initiation of these seizures. This would explain their generalized onset and also the lack of abnormalities in the interictal electroencephalogram. In the past few years there have been increasing doubts about the importance of the "centrencephalic" structures in the production of seizures. In effect, only rarely have there been anatomical lesions described in these structures of patients with "centrencephalic" seizures.[2] Also there is much evidence pointing to the relatively high seizure threshold of the thalamus and adjacent areas. Some experiments carried out on cats have shown that generalized seizures electrically and clinically indistinguishable from a centrencephalic attack can be produced with bilateral cortical epileptogenic lesions, as long as the corpus callosum remains intact, and even after destruction of the thalamus, hypothalamus, rostral mesencephalon and rostral hippocampus.[3]

It is known that any normal individual may have a generalized seizure in the presence of appropriate circumstances. Focal seizures, on the other hand, are rarely seen in normals. Fast intravenous injection of metrazol, for example, will induce a grand-mal convulsion in any normal subject. Sudden withdrawal of certain drugs may have a similar effect. And sometimes addition and interaction of several otherwise innocuous stimuli may produce a seizure in subjects with lower than normal threshold.

Thus it can be seen that distinguishing between a grand-mal seizure and a secondary major motor attack has immediate practical importance. This distinction is often very difficult to make, but when it can be made it is helpful in terms of prognosis and treatment. In general, a focal seizure requires an extensive investigation of its cause to avoid missing some progressing lesion that might be treatable and perhaps curable at the onset but not later. The extension and depth of the diagnostic work-up will depend on circumstances inherent in each individual case. Seizures starting after 20 years of age warrant more diagnostic effort than those starting in childhood or adolescence. Focal elements detected either from the clinical history or examination or by the electroencephalogram generally require a more exhaustive work-up than grand-mal convulsions.

Management

One single major motor seizure requires no treatment and its management should be limited to the protection of the patient from injury (falling, biting tongue or lips, etc.) and from other harmful events like aspiration of secretions or respiratory obstruction from the swallowing of dental prostheses. Any anti-

convulsant given during or immediately after the attack will at best prevent its repetition but will not alter the course of the seizure, once it has started. It is imperative, however, that an investigation of the cause of the convulsive attack be started as soon as possible.

In the final analysis, regardless of the depth and thoroughness of the investigation, a large number of cases fail to reveal a sufficient cause for the seizure. But, unless the electroencephalogram is grossly abnormal, the occurrence of one single major motor seizure does not warrant treatment, since once started and even assuming that no more attacks occur, anticonvulsant therapy should be continued for two or three years, and only then should the dosage be gradually decreased.

Furthermore, many individuals never have more than one seizure in their life. Therefore, once the physician is satisfied that he has carried out the investigation as far as his judgement and knowledge tell him is necessary and has still not found the cause, he is justified in waiting while he watches his patient closely. Only in those cases in which there is no way of following the patient or of referring him to a reliable physician is it best to start anticonvulsant treatment. But once this is decided upon, there is no point in doing it halfway; because insufficient dosage will not help but may, on the contrary, produce side effects and other inconveniences attached to prolonged treatment. Once anticonvulsant treatment is started, it should be instituted with a full therapeutic dose and with the prospect of a two to three years' span of treatment. The patient should be warned of the danger involved in sudden withdrawal of anticonvulsants, so that he is fully aware of his own responsibility in maintaining the regularity and adequacy of dosage, as prescribed by his treating physician.

Life's Speed?

We have cherished and preserved a host of couplets and proverbs from the past, intended to urge our more lethargic forefathers to get on the ball and get some work done. Things like Franklin's classics: "Dost thou love life? Then do not squander time, for that is the stuff life is made of." And, "Never leave that till tomorrow which you can do today." We've preserved the stories about the grasshoppers and the ants. And in sundry and subtle ways we urge young and old alike to work faster and to squeeze each minute a little harder—to make hay while the sun shines, and to save up for a rainy day.

We've learned to abhor laziness, and to judge a man by the number of bathrooms in his home. We've been praised for our achievements and scorned for our failures. And still we crack the whip and drive the tempo faster, while the echo of one small voice lingers in the distance: the contention of the late Mahatma Gandhi that "there is more to life than increasing its speed."*

Our greatest pretenses are built up not to hide the evil and the ugly in us, but our emptiness. The hardest thing to hide is something that is not there.—Hoffer

HOW TO TURN YOUR RECEPTIONIST INTO AN INSTANT INFORMATION RETRIEVER

You have a problem: no matter how faithfully you read your professional journals, you still waste hours tracking down the article you need now.

Forget it!

New Instadex frees you from searching out key reference information. In seconds your receptionist can hand you summaries of all the right articles from every journal you follow. You can then go straight to the article that interests you and spend your time reading instead of searching.

Instadex was developed by a practicing internist who discovered—just as you have—that he was spending too much time hunting down half-remembered reports. Based on *Index Medicus'* subject analysis, this new system is so completely cross-indexed you cannot miss finding the article you want.

What's more, Instadex reaches you ready for immediate use. *You* do no processing or arranging. Instadex requires *no* filing. (Your girls will bless you for that!) In fact, Instadex supplements or completely replaces whatever card file you now maintain.

In mere seconds your receptionist hands you every reference in your file on the Guillain-Barre' syndrome.

If the Instadex system saves you just four hours a *year* it will have paid for itself! We'll bet it'll save you four hours a month . . . or even more.

Ask your receptionist to write today for detailed information and prices. Why waste time fishing for information when you've other fish to fry?

INSTADEX

104-A TWELFTH AVENUE SOUTH
SOUTH ST. PAUL, MINNESOTA 55075

(New TUBEX® are constantly being added)

Only TUBEX® offers so complete a line of closed system injectables

and it's still growing.

To meet your present needs more precisely, the Tubex line comprises 37 different products in 69 dosage variations. And more are on the way.

Tubex offers these unit dose advantages:

- **accuracy**—premeasured, clearly labeled to help ensure correct medication
- **convenience**—no filling, no needle-sharpening, no sterilization, no cleanup
- **simplicity**—precision-made, well balanced syringe breech loads in seconds, permits easy aspiration
- **reduces risk**—single-use cartridge-needle units reduce risk of cross contamination; less chance of spillage reduces risk of contact sensitization for doctor or nurse
- **stability**—glass cartridges can't deteriorate or react with medication
- **acceptability**—presharpened, siliconized needles lessen pain of injection; patients appreciate single-use equipment

Just select, inject, throw away

Centrally Herniated Intervertebral Disks*

Acute Spinal-Cord Compression

ALFRED UIHLEIN, M.D.†
HILLIER L. BAKER, JR., M.D.†
Rochester, Minnesota

CENTRALLY HERNIATED intervertebral disks can occur in the cervical, thoracic, and lumbar vertebral regions. In the lumbar region they may result from chronic disk degenerative disease or spondylosis, with or without antecedent trauma. In either degenerative disease or spondylosis, compression of the elements of the spinal cord or the cauda equina by a slowly progressive lesion does not produce the severe neurologic deficit that results from an acute lesion. Thus the recovery from the deficit produced by the acute lesion is not as prompt or gratifying as that found with a chronic, slowly progressive, midline disk herniation. Fortunately the incidence of centrally herniated intervertebral disks is small, but such a lesion does produce characteristic neurologic changes.

Cervical

Causative Factors

Centrally herniated disks in the cervical region are encountered most frequently in conjunction with acute trauma or spondylosis.[1-3] A "whiplash" injury may produce cervical spondylosis, with the concomitant production of a centrally herniated soft disk. A "hangman's fracture" of the cervical vertebra may likewise produce an acute centrally herniated disk. This fracture of the cervical spinal column is characterized by a bilateral fracture through the neural arch of the second cervical vertebra, with or without dislocation of the body of the axis on that of the third cervical vertebra.[4]

Early Treatment

When an acute centrally herniated disk occurs in conjunction with trauma to a cervical vertebra, varied degrees of paraparesis or quadriplegia with a fluctuating sensory level is seen early clinically. Unless decompression of the common dural sac by surgical means is not carried out promptly, with the removal

*Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.

†Mayo Clinic and Mayo Foundation: Sections of Neurologic Surgery and of Roentgenology.

of the herniated disk, irreparable neurologic deficit may result. This type of decompression should be done under skeletal traction to the skull in order to stabilize the cervical column as much as possible while a posterior decompressive laminectomy or an anterior spinal-cord decompression is being done to avoid further damage to the cord during surgery. If intact, the dura mater should not be opened to facilitate removal of the soft disk material in front of the cord, but rather this material should be removed by use of an adequate bilateral exposure; thus the cerebrospinal fluid surrounding the cord can act as a protective sheath to an already edematous cord, which is the result of trauma due to the central herniation. Removal of disk fragments with an intact dura may prevent undue manipulation of the cord, which could be an important factor in the eventual outcome of surgical intervention.

Surgical Intervention

There are those who advise that surgical intervention in the face of an acute neurologic deficit due to a centrally herniated cervical disk accomplishes little if there is no evidence of a spinal subarachnoid block on lumbar puncture or by myelography with contrast medium. This is not necessarily true. If the validity of these tests is in doubt, surgical exploration can best determine the extent of cord damage. Sometimes the advantages gained from direct observation of the amount of cord compression at surgery outweighs the apparent advantages gained from procrastination. Some believe that skeletal traction alone to the cervical spinal column may reduce an acute centrally herniated disk sufficiently to decrease the neurologic deficit with the passage of time; however, any deterioration in the neurologic examination during a 24- to 48-hour period of observation justifies exploration.

A neurologic examination to determine which cervical nerve roots are primarily involved is essential (Figure 1) so that adequate decompression of the nerve-root sleeves and contiguous spinal cord at the correct level can be done at surgery.[3] The transdural removal of a centrally herniated disk should be reserved only for those situations in which the disk material has ruptured through the ventral dura and presented in the subarachnoid space. A posterior fusion operation should be deferred at this time, because preparation of the bed could damage the cord further either by indirect trauma or by extradural pressure from a clot that results from bleeding in bone secondary to the preparation of the bed for the bone graft.

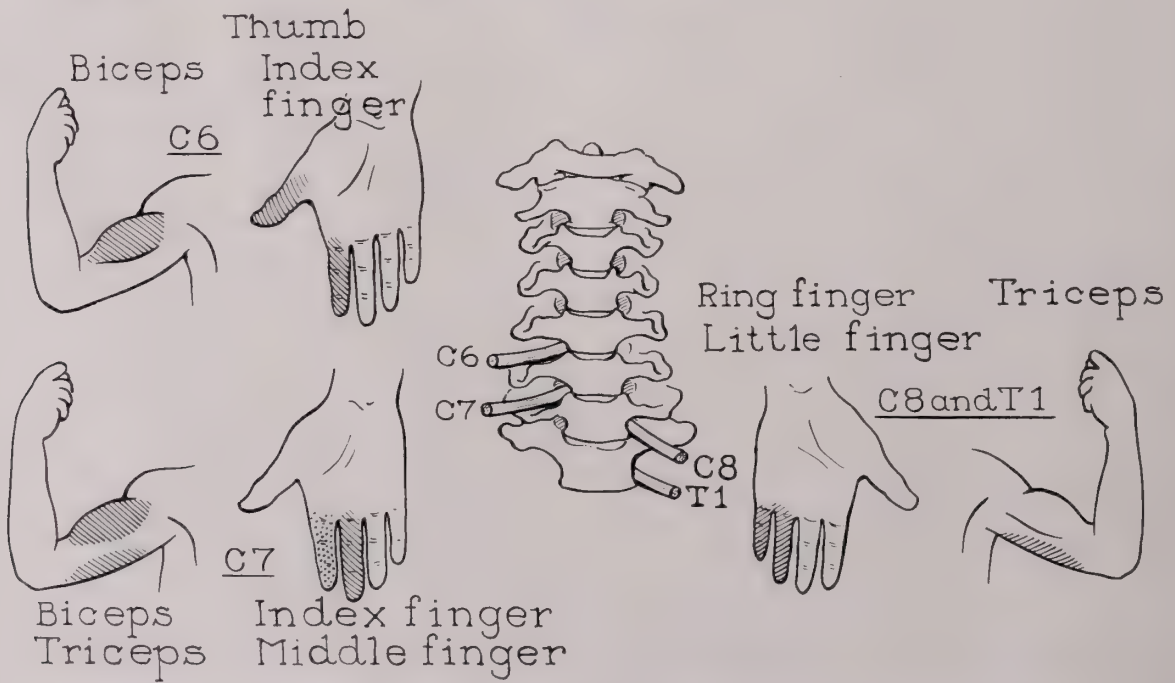

Fig. 1—Diagram of neurologic changes associated with compression of the cervical nerve root.

Thoracic

Progressive Onset of Symptoms

Protrusion of an intervertebral disk in the thoracic region occurs infrequently when compared to protrusions in the lumbar and cervical vertebral column.[5,6] Trauma may or may not be a contributing factor, and protrusions have occurred at every vertebral level. In cases of trauma, the patients may not lose the use of their lower extremities initially, but the progressive loss of sensation or locomotion over a period of time necessitates surgical intervention. Surgery may not result in improvement, but undue delay may produce permanent damage to the spinal cord.

The most common presenting symptoms are pain and numbness associated with some difficulty in locomotion.[7,8] Paresthesias and perverted sensations predominate, and pain may be located in the thoracic or low-back regions.

Objective Finding

Roentgenograms of the thoracic vertebrae may show evidence of calcification of the thoracic intervertebral disk that is producing the symptoms;[9] however, this region of calcification may not be the one that is producing cord compression. Myelography with contrast medium may show a specific defect in the anteroposterior projection at one (Figures 2 *A* and *B*) or more levels (Figure 3) that is characteristic and will exclude the possibility of a cord tumor or other lesion.

The protein level of the spinal fluid may be increased in thoracic-disk protrusions.[6] Sur-

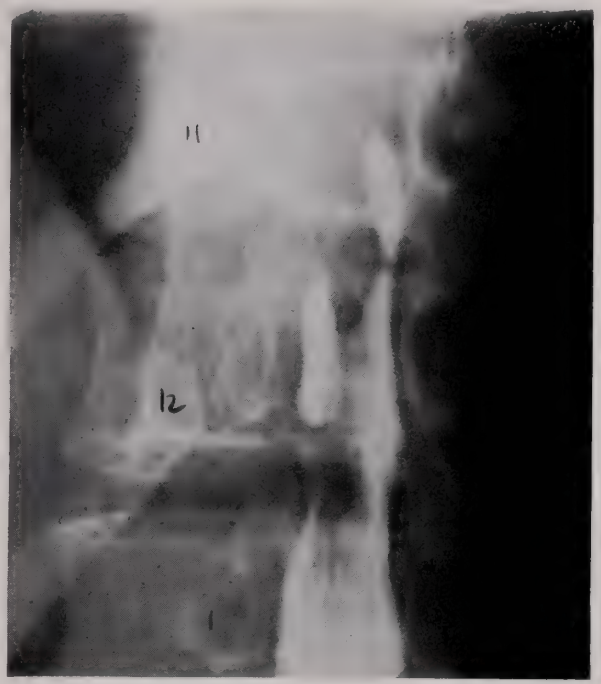

Fig. 3—Multiple defects in contrast-medium column due to centrally protruded thoracic disks.

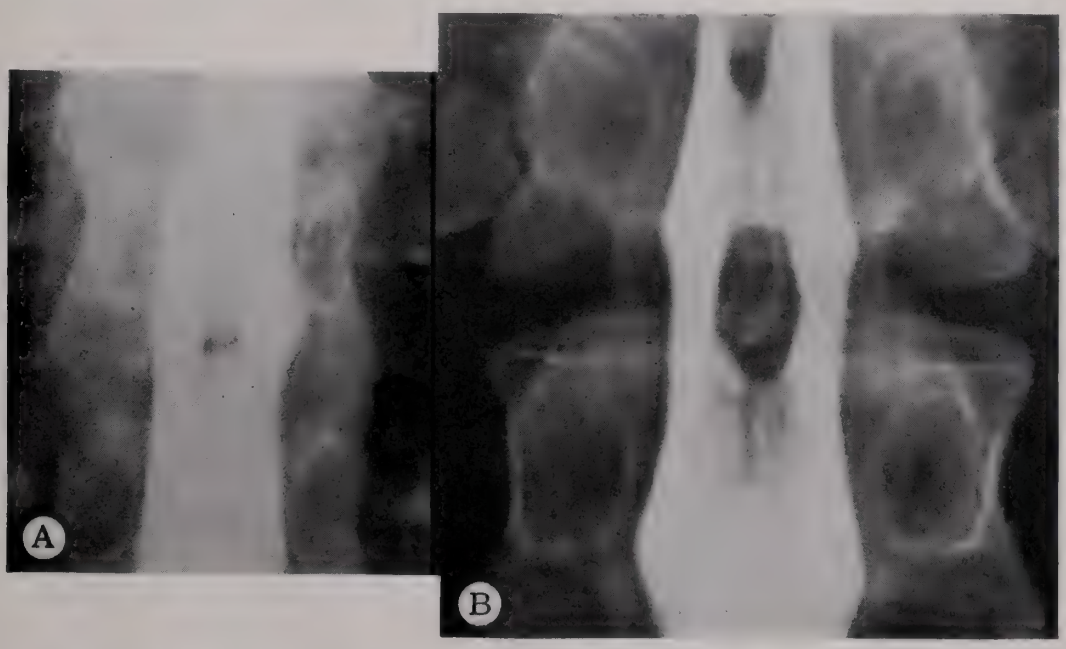

Fig. 2—*A* and *B*, Defect in contrast-medium column due to centrally protruded thoracic disk. (From Baker, H. L., Jr., Love, J. G., and Uihlein, A.: Roentgenologic Features of Protruded Thoracic Intervertebral Disks. Radiology 84:1059, 1965. By permission of The Radiological Society of North America, Inc.)

gical results in these cases may be discouraging because prolonged cord compression has produced irreversible changes. After laminectomy and decompression, the neurologic status may not be altered and may even be worse, as reported by some.[8] A lateral approach to the disk region (costotransversectomy) has been reported[10] as reducing the danger of increasing the neurologic deficit after operation because the cord is in less danger from direct trauma. Nonetheless, the surgical results may be less fruitful than anticipated. Careful patient selection is important.

Lumbar

Centrally herniated intervertebral disks in the lumbar region generally occur below the level of the conus medullaris and compress the roots of the cauda equina; this represents a peripheral nerve type of injury. In acute compression of the cauda equina, the need for surgical intervention should not be questioned. Compression of the roots secondary to trauma to the bone or secondary to a protruded intervertebral disk should be prompt in order to prevent progressive loss of nerve function of the cauda equina. In degenerative disk disease the degree of neurologic deficit cannot be assessed adequately without an accurate patient history and careful neurologic investigation (Figure 4). Progressive weakness, even in the presence of decreasing pain, justifies a positive approach to avoid further motor loss both to the extremities and to sphincter control. Roentgenograms of the lumbar spinal column and myelograms with contrast medium may be required to determine the compression level and to exclude other causes of a cauda equina lesion.[11-14]

Recently Love and Emmett[15] have reported the incidence of prolonged periods of urinary retention in women relieved by the removal of an "asymptomatic," protruded, lumbar intervertebral midline disk.

Comment

The acute compression of the cervical or

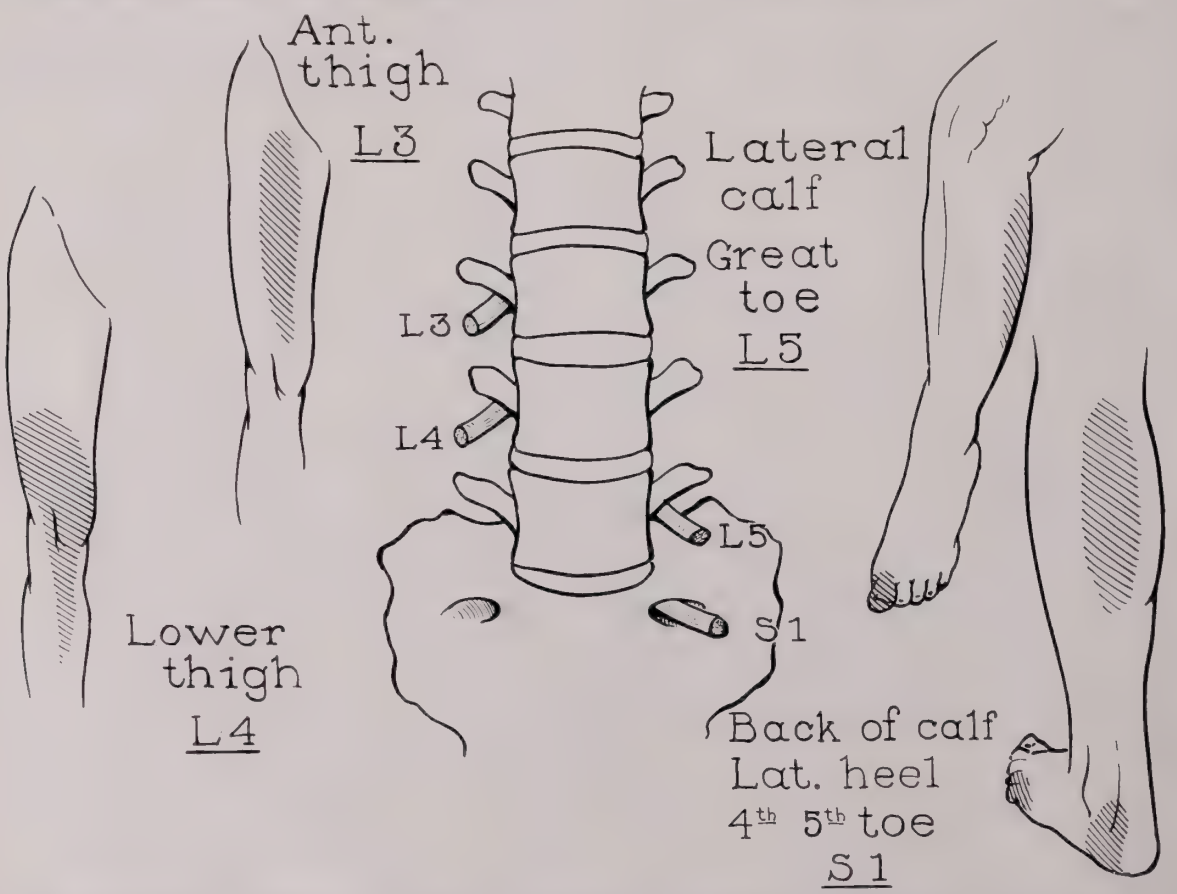

Fig. 4—Diagram of neurologic changes associated with compression of the lumbar nerve root.

thoracic cord as well as the cauda equina by a centrally herniated intervertebral disk may constitute an emergency because of progressive neurologic deficit. Early surgical intervention with decompression of the dural sac and its contents may prevent paraparesis or quadriplegia, depending solely on the amount of cord damage that occurred prior to surgery. This is especially true in lesions affecting the cervical and thoracic regions of the spinal cord.

Considerable difference of opinion still exists in the management of cervical spondylosis, when the degree of cord involvement is slowly progressive. The question revolves around whether decompression of the cord by a posterior translaminal approach, as Scoville[2] has recommended, is preferable to decompression by anterior cervical intervertebral disk removal and fusion.[16] The associated hypertrophic ridges and spurs can be removed more readily by the anterior approach; however, when multiple intervertebral disk levels are involved, the anterior approach has not been as successful as the posterior approach in decompressing the common dural sac. Certainly in midline disk protrusion associated with spondylosis (unless some form of decompression is carried out), a serious quadriplegic neurologic deficit may eventually develop. The ideal surgical approach has not been found. Connolly, Seymour, and Adams[17] in 1965 summarized their experience with anterior cervical fusion as follows: "It is our belief that this operation will gradually find its proper place in the treatment of degenerative cervical disc disease. The results in this carefully evaluated series do not, however, justify the degree of enthusiasm expressed for this operation in some earlier reports."

The taking of a careful history and a neurologic examination in these cases are essential to a correct interpretation of the underlying cause of the patient's complaint. Excellent radiographic studies utilizing tomography and cineradiography may be more informative than contrast-medium myelography or diskography, in both of which correct interpretation may be difficult. The surgeon must not allow these myelographic alterations to predominantly influence the manner of management without correlating these findings with the history and clinical examination.

Finally...a salicylate superior to aspirin?

Not at all, Doctor...but

magan®

(magnesium salicylate, W-T)

should be considered for your arthritic and rheumatic patients who cannot tolerate aspirin.

Surveys * made in 1966 and 1967 among private practice physicians showed an incidence of intolerance to aspirin ranging from 3-85%. The majority of physicians surveyed reported an intolerance in 10-30% of their patients.

How does this compare with your experience?

*by two independent national research organizations

WARREN-TEED PHARMACEUTICALS INCORPORATED
COLUMBUS, OHIO 43215
SUBSIDIARY OF **ROHM AND HAAS COMPANY**

10-30

Don't use Magan on all your patients–

consider Magan for those patients who cannot take aspirin because of gastric discomfort

Private Practice Physicians tried Magan on almost 700 patients whom they judged intolerant to aspirin and other salicylates.

The majority of these patients could take Magan and obtain the benefit of salicylate therapy.

magan® **an alternate salicylate**

(magnesium salicylate, W-T)

May be tolerated by some persons intolerant to aspirin by reason of gastrointestinal irritation.

Magan is a new salicylate product from Warren-Teed.

A single chemical entity . . . no coating, no buffering, sodium free and non-acetylated.

Composition: Each orange colored tablet contains 5 grains (approx. 325 mg) of magnesium salicylate.
Dosage: 1 or 2 tablets every 4 hours with a full glass of water.

"Now that your acne is clearing up nicely, it might be a good idea if you started losing some weight."

Get them while they're easily reversible.

Obesity doesn't happen suddenly. This insidious process has its beginning—and the chances of reversing it are better—during the *first 10 to 15 pounds of weight gain.* When a new dietary pattern must be established, consider the adjunctive use of BAMADEX SEQUELS. Combining the proven *anorexigenic* action of d-amphetamine with the *tranquilizing* effect of meprobamate, BAMADEX SEQUELS controls appetite throughout the day, usually with a single capsule daily.

Contraindications: Dextro-amphetamine sulfate: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.
Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.
Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness. Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Bamadex® Sequels®

Dextro-Amphetamine Sulfate (15 mg.) with Meprobamate (300 mg.) Sustained Release Capsules

Spinal Cord Compression Secondary to Neoplasms*

DON M. LONG, M.D., PH.D.†
Minneapolis, Minnesota

A 42-YEAR-OLD MAN was in good health until he noted a dull back pain which appeared after an accident in which his wife was run over and he himself barely escaped injury by throwing himself violently backward. The pain soon localized to the left subscapular area, was continuous, and was accentuated by movement. A diagnosis of traumatic intercostal neuralgia was made. When no relief was obtained by the usual conservative measures, a diagnosis of thoracic aneurysm was entertained. He successively consulted several physicians while becoming progressively incapacitated by pain. He became so irascible that his sanity was questioned, and the pain was thought to be of psychogenic origin. Three years after the onset of pain his left leg became weak. Subsequent paresis of the right leg was followed by loss of sensation and finally urinary retention. Mental symptoms were so prominent that "shock" therapy was advised. Before this step was taken, however, neurological consultation with an eminent neurologist was obtained. Examination revealed a spastic paraparesis of four months' duration with a T-6 sensory level, clonus, hyperactive reflexes, loss of bowel and bladder function and a urinary tract infection. Pain was so severe that the patient could not bear to be moved. A diagnosis of left-sided intraspinal neoplasm in the high thoracic region was made. Referral was made to an equally eminent neurosurgeon. Laminectomy of the T4-T6 area revealed no tumor; however, encouraged by the neurologist, the surgeon extended the limits of the incision and encountered an intradural extramedullary neurofibroma which was totally removed. Within one week recovery of sensation had begun, and one year later recovery of neurological loss was complete.[9]

This illustrative case report of a patient treated by William Gowers and Sir Victor Horseley, which sounds surprisingly current, represents the first spinal-cord tumor successfully diagnosed and treated. Prior to this demonstration of the feasibility of the diagnosis and removal of spinal-cord neoplasms, only 58 cases of cord tumor had appeared in the medical literature. McEwen had successfully performed laminectomies for other disease, but the operation was generally held to be impossible, and the prognosis of spinal-cord tumor was considered hopeless.[3] Following Horseley's surgical feat, such procedures rapidly became routine, and only thirty-seven years later Elsberg was to write a definitive mono-

graph detailing 100 operative cases and providing much of the clinical information in use today.

Anatomy

The spinal cord lies completely encased within the bony vertebral canal. There are seven cervical, 12 thoracic and five lumbar vertebrae with the five sacral and four coccygeal bodies being fused into separate single bones. Corresponding to these vertebrae are 31 spinal-cord segments and pairs of nerves, eight cervical, 12 thoracic, five lumbar, five sacral and one coccygeal. Since there are eight cervical segments and only seven cervical vertebral bodies, each cervical nerve exits from the spinal column above the vertebra of corresponding number, with the C8 nerve lying between C7 and T1. Beginning with the first thoracic nerve all nerves pass out below the vertebra of like number.[2]

Vertebra vs. Cord Level

Because of a disparity of growth the end of the spinal cord lies between L1 and L2 in the adult. The following rule may be applied to determine the probable level of cord involvement when the region of bony abnormality is known. C1 vertebral involvement means C1 cord involvement. Between C2 and T10 add 2 to the vertebral number to give the cord segment. That is, C4 vertebra means C6 cord, T8 vertebra means T10 cord, and so on. All the lumbar segments lie opposite the spinous processes of T11-12, and all the sacral and coccygeal segments are at L1 and below.[2,5]

Vascular Supply

The major vascular supply of the cord is through the single anterior spinal artery which arises through fusion of paired branches of the vertebral arteries and is reinforced by a varying number of segmental arteries below. In addition, paired posterior spinal arteries follow a wandering course in the posterolateral sulcus, supplying the posterior columns and posterior horns. The anterior two thirds of the cord is supplied by the anterior spinal artery via central penetrating branches or circumferential pial vessels.[2]

The system of vertebral veins is very complex. There are extensive venous channels in and on the cord which communicate with a dense epidural plexus which connects with segmental veins of neck, thorax and abdomen, providing a ready pathway for metastatic or inflammatory disease to reach the intraspinal compartment.[2]

The Afferent System

Localization of cord compression is based primarily upon the effects of this compression on a few major spinal tracts. The afferent systems which are clinically most useful are as follows. The posterior white columns subserve the ipsilateral side of the body and carry *position and vibratory sense* as well as touch. Lesions of this area cause deficits on the same side of the body below. The lateral spinothalamic tract lies in the anterolateral quadrant and carries *pain and temperature sensation* from the opposite side of body. The ventralspinothalamic tract is concerned with *light touch and is also a crossed tract* serving the opposite side of the body. It is found in the anterior white columns. However, it is not the only pathway subserving touch; this modality is probably represented in several different areas and is therefore a less accurate measure of level of involvement than pain sensation.

The Efferent System

Efferent systems of value are the corticospinal and the sympathetic tracts. As neither tract crosses in the spinal cord, lesions produce ipsilateral deficits. The corticospinal tract is located in the posterolateral quadrant. Corticospinal lesions result in *motor weakness, increased stretch reflexes, absent cutaneous reflexes, and extensor toe signs.* Sympathetic interruption produces *loss of sweating* below the lesion, fall in blood pressure and poikilothermia.* Sympathetic fibers are located central to corticospinal and lateral spinothalamic areas and near the junction of posterior and anterior gray horns.[2]

Pathology

Spinal-cord tumors are traditionally classified into (1) extradural, (2) intradural-extramedullary, and (3) intramedullary. Individual tumors have some unique characteristics, but generalities can be induced. These tumors are

*See Test Your Word Score Page 1213.

predominantly found between ages 30 to 60 years, though they occur in all decades. There is no sex differential except with a few specific tumors. There is no site of predilection; most are found in the thoracic region simply because it is longer. Cord tumors are not common, representing about 0.4 percent of autopsies and about two percent of tumors in general; but the increased longevity of cancer patients is steadily increasing the incidence of metastatic intraspinal lesions. Cord tumors are about one-sixth as frequent as brain neoplasms.[1,3,4,8]

Extradural Tumors

Extradural tumors represent about 22 percent of the total of primary spinal-cord tumors, a percentage depending greatly upon the patient population involved. Where cancer incidence is high, the frequency of extradural neoplasms has been reported to be considerably higher.[1] As intimated, the majority of these tumors are metastatic. The most frequent primary lesion is carcinoma of the lung, with breast, prostate, gastrointestinal tract, thyroid and kidney following. Sarcomas, chordomas, and lymphomas of various types complete this list. Chordoma merits special notice since the majority of the tumors arise in the sacral region and attain huge size prior to recognition. They may grow in the extradural space, compressing nerve roots, even reaching the lower spinal cord.

Inflammatory lesions of the extradural space may develop into well-circumscribed abscesses with cord compression. *Granulomas from tuberculosis or syphilis* are no longer common, but fungal granulomas are increasing in frequency. Spontaneous epidural hemorrhage may mimic spinal-cord tumor. The precipitating cause is usually anticoagulation or a blood dyscrasia. If large enough the ridges of cervical osteoarthritis may mimic a spinal-cord neoplasm in symptoms and signs.

Intradural-extramedullary

Intradural-extramedullary tumors usually arise from the leptomeninges and nerve root sheaths. Meningiomas and neurofibromas account for about 85 percent of the group, while this classification of tumors represents about 55 percent of the total of spinal-cord tumors. Arteriovenous malformations, dermoids, and metastatic brain tumors are less common lesions. Ependymomas of the filum terminale (the so-called "giant tumor of the cauda equina") arise from a collection of ependymal cells near the tip of the conus medullaris and are the third most frequent tumors of this group.[3,4,6]

Neurofibromas are the most common tumor and are frequently dumbbell in shape with a large extradural or even extraspinal portion. They are frequently present in association with von Recklinghausen's disease and may be multiple.

Meningiomas are only slightly less common than neurofibromas. They occur most frequently in the thoracic area in women.[5] They may be found at any point but are usually near the exit of the spinal nerve.

Vascular malformations are most common in the thoracolumbar area and are usually both extra- and intramedullary. They may cause symptoms by compression, by thrombosis with cord infarction, or by hemorrhage.

Dermoids are primarily tumors of children. They are usually associated with a lumbar sinus tract, lipoma, or hair patch. It is important to remember that any such external lesion may indicate a tumor and that the tumor may be located at any level from the skin lesion to the conus medullaris. Meningitis is a frequent complication of these tumors.[8]

Intramedullary Tumors

Intramedullary tumors are predominantly gliomas. Nearly 50 percent of these lesions arise in the lumbar region. Ependymoma is the most common histological type; astrocytoma is second; any of the other gliomas may occur as a rarity, with glioblastoma, oligodendroglioma and medulloblastoma being most frequent. Vascular malformations occur as described. Syringomyelic cysts may result from intramedullary gliomas and mimic benign syringomyelia for an extended period.

Signs and Symptoms

It is apparent from the variety of possible lesions that the symptoms and signs of spinal-cord tumors will be equally variable; nevertheless, classifications of constellations of symptoms and signs are possible. The course of these neoplasms is usually slow and con-

tinuous, though acute presentations do occur, as do remissions and exacerbations. There are basically four general methods of presentation and progression, based upon the predominating symptoms with much overlap: (1) radicular pain followed by ipsilateral motor and contralateral sensory loss proceeding to bilateral motor-sensory loss with impairment of bowel and bladder function; (2) unilateral paresthesias with contralateral motor and sensory loss progressing to complete paraplegia; (3) severe back pain of long duration followed by motor, sensory and sphincter disability, and (4) loss of motor function followed by sensory and sphincter disturbances without pain.[3,4] These groups may be further subdivided into *segmental* and cord *compression* symptoms.

Segmental Symptoms

Fortunately the favorable neurofibromas and meningiomas frequently announce themselves by radicular pain, often continuous, increased by straining, and worse at night. The pain may mimic visceral disease, and about 10 percent of patients with intraspinal neoplasms are mistakenly operated upon for an abdominal lesion. Root or anterior horn cell compression may lead to other segmental symptoms; muscle atrophy, fasciculations, loss of reflexes, and radicular sensory loss.

Compression Symptoms

The signs of cord compression are rarely symmetrical; characteristically, impaired motor function on one side and pain-temperature sense on the other are found early. Touch is affected later. The motor loss is typically spastic and greater in flexors than extensors. Stretch reflexes are usually increased; clonus and Babinski signs are present. Proprioceptive or posterior column function is impaired more on the side of greatest cord involvement. Pain and temperature sense and light touch are usually more distally affected, and loss becomes less evident near the level of the lesion. A zone of radicular hyperesthesia may cap the anesthetic area. Sweating is usually decreased below the level of the lesion. Bowel and bladder dysfunction also occurs routinely.[3,4,7]

It is very difficult to clinically distinguish extradural from intradural - extramedullary lesions. However, the differentiation of these two groups from intramedullary tumors is usually possible on the basis of the neurological manifestations.

Intramedullary Symptoms

With intramedullary neoplasms the course is frequently prolonged. Sensory and motor loss may predominate segmentally near the lesion. Perianal sensory sparing is common. Pain is rare. Anterior horn cells are often involved. Corticospinal tract impairment is late. Bowel and bladder dysfunction occurs in the last stages of the tumor development. Spinal block is rare and late.

Extramedullary Symptoms

With extramedullary lesions radicular pain is common, the sensory loss is uniform, motor loss and bladder dysfunction occur early. Spinal block is much more likely to appear at an early stage in the disease.[3,4]

Diagnosis

It should be apparent that the diagnosis of cord tumor is usually suspected from the history and examination. X-rays of the spine may show bony destruction or erosion, loss of pedicles, or widening of the spinal canal. Metastatic tumors commonly destroy bone, and pathologic fractures are common. Myelography is usually necessary to establish the diagnosis. Extradural tumors can be recognized by ragged appearance of the edge of the dye column as it attempts to pass the obstruction. Intradural-extramedullary tumors are usually sharply circumscribed and separate from the spinal cord. Intramedullary tumors present with widening of the spinal cord.[3,4]

Occasionally it will be of value to perform simultaneous cisternal and lumbar punctures to put dye above and below the lesion for complete delineation of upper and lower margins. Finally, it should be remembered that preparations for surgery should be made prior to myelography in any cord tumor suspect, for sudden decompensation following lumbar puncture is not uncommon. Lumbar puncture before myelography is rarely indicated. If it is performed, however, the spinal fluid protein will frequently be elevated. The Queckenstedt test for spinal blockage is of little use in the diagnosis of spinal tumors.

Differential Diagnosis

The list of possible lesions simulating spinal-cord tumor is formidable and far too extensive for complete review. In general terms, infectious myelitis, toxic myelopathy, trauma, vascular disease, intervertebral disc disease, metabolic conditions such as diabetes mellitus, demyelinating diseases, and developmental defects are the major categories to be considered.[7]

Treatment

The treatment of spinal-cord tumors is primarily surgical. Certain tumors may receive irradiation or chemotherapy after operative decompression, but if there is evidence of cord compression surgery must precede other therapies in most instances. Ideally treatment should be instituted while symptoms and deficits are minimal. However, it must be stressed that speed is of the utmost importance once profound neurological loss has occurred. The faster the cord can be decompressed, the better the chance of recovery. Several other factors are also involved in recovery. A long history of slow development of neurological loss is more favorable than a short one. Paraplegia of rapid onset is less likely to recover than a deficit which has taken several days to develop. Complete loss of function is less apt to improve than incomplete. Paraplegia of more than 72 hours' duration is usually hopeless Nevertheless, with any of these histories, no matter how favorable or unfavorable, it is urgent that treatment proceed to give every chance for recovery of function. The aim of treatment is to remove the tumor, relieve pressure on the spinal cord or roots, and alleviate blockage of spinal fluid circulation. Complete removal may not be possible, but unless the latter two conditions are met, improvement is unlikely.

Extradural Tumors

In general, extensive laminectomy with relief of spinal block and cord compression is the treatment of choice. Metastatic tumors should be operated upon to prevent paraplegia unless the patient is terminal with widespread metastases. Only partial excision of the tumor is usually possible. Postoperatively x-ray therapy or chemotherapy is frequently given.

Inflammatory collections are drained and appropriate antibiotics given. The sacral chordomas are a special problem, but with radical excision, cures may be expected. Hematomas simply require evacuation.

Intradural-extramedullary Tumors

The majority of the neurofibromas and meningiomas can be completely removed and so cured. Giant ependymomas of the filum terminale may also be totally excised. If total removal is impossible, then x-ray may benefit the ependymomas. Dermoids are curable lesions; but great care must be taken not to spill the contents into the spinal fluid, for a chemical or bacterial meningitis may develop. The vascular malformations may only rarely be removed totally. Recently it has been shown that ligation of feeding vessels after their identification by selective aortography may benefit these patients. Currently this is being performed only after severe neurological loss which incapacitates the patient. The technique may prove useful in these discouraging cases.

Intramedullary Tumors

These are the most difficult of spinal cord lesions with which to deal. For many years decompression and irradiation with evacuation of cysts was the only effective treatment. However, with the use of two-point coagulation, microsurgery, or the operating microscope, many of these lesions can now be excised without significant spinal-cord damage. In order to totally remove these lesions a two-stage technique is sometimes advantageous. The first stage consists of laminectomy and myelotomy; at the second operation a week or so later, the tumor will often have delivered itself through the myelotomy site, facilitating removal. If removal is incomplete, x-ray therapy is usually given postoperatively.

Syringomyelic or hematomyelic cavities can be drained or opened to allow continued release of contained fluid. X-ray is of no value for syringomyelia unless the cavity is caused by an intramedullary glioma.

Conclusions

In summary, it may be stated that spinal-cord neoplasms characteristically present with two types of symptoms, radicular and cord-

compression.

Extradural tumors are most likely metastatic or lymphomatous.

Intradural-extramedullary tumors are usually neurofibromas or meningiomas.

Intramedullary tumors are commonly ependymomas or astrocytomas.

Whatever the nature of the lesion or the mode of onset of symptoms, once signs of spinal-cord compression appear an emergency situation exists. Diagnosis and therapy must follow as rapidly as possible. Accurate diagnosis requires, in addition to neurological examination, spine x-rays and usually myelography. Prompt surgical excision of the lesion is mandatory if return of function is to be expected. It is worth reemphasizing that in our series of spinal-cord tumors, 41 percent were benign and removable, while an additional 15 percent were potentially curable (Table). This high percentage of curable lesions makes prompt diagnosis and treatment even more imperative.

TABLE
University of Minnesota Spinal-Cord Tumors
(250 cases operated upon)

14%	Meningioma
15%	Neurofibroma
32%	Metastatic
11%	Intramedullary glioma
4%	Arteriovenous malformation
12%	Other benign
12%	Other malignant

WALLENBERG'S SYNDROME

This syndrome is caused by occlusion of the posterior-inferior cerebellar artery, resulting in sensory and sympathetic disturbances. Cerebellar and paramidal tract signs and evidence of partial involvement of the 5th, 9th, 10th, and 11th cranial nerves are usually seen.

It is most often associated with vertigo which may result in falling. There may be nausea, vomiting, ipsilateral ataxia, muscular hypotonicity, past-pointing, lateropulsion, and other cerebellar signs.

The physical examination may reveal facial paresthesias, homolateral nystagmus, hiccough, dysphasia, dysphonia, dysarthria, and diplopia. Horner's syndrome is almost invariably present.

The syndrome is usually seen in the arteriosclerotic patient. Some patients may recover within a few months, but other patients may be left with neurologic residuals.

There is a great deal of difference between the eager man who wants to read a book and the tired man who wants a book to read.—Gilbert Chesterton

ACHROMYCIN® WORKS HERE
TETRACYCLINE

Effectiveness: ACHROMYCIN Tetracycline is a crystalline broad-spectrum antibiotic which provides effective therapeutic activity against susceptible microorganisms.

Contraindication: History of hypersensitivity to tetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated and, if therapy is prolonged, serum level determinations may be advisable. Some patients may develop a photodynamic reaction to natural or artificial sunlight. Those with a history of photosensitivity reactions should avoid direct exposure to sunlight while under treatment. Discontinue drug at first evidence of skin discomfort.

Precautions: Use may result in overgrowth of nonsusceptible organisms. Constant observation is essential. If new infections appear, take appropriate measures. Use of tetracycline during teeth development may cause discoloration of teeth.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes (a case of exfoliative dermatitis has been reported); photosensitivity reaction, onycholysis and discoloration of nails (rare). Kidney—rise in BUN, apparently dose-related. Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. In young infants, bulging fontanels have been reported following full therapeutic dosage. This symptom has disappeared rapidly when drug is discontinued. Teeth—dental staining (yellow-brown) in children of mothers given tetracycline during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. Blood—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. Liver—cholestasis (rare), usually at high dosage. Tetracycline may form a stable calcium complex in bone-forming tissue. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: One Gm. per day, in 4 divided doses of 250 mg. each. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

ACHROMYCIN® WORKS HERE
TETRACYCLINE

Actually ACHROMYCIN works wherever the infection is due to an organism your lab cultures have shown to be tetracycline-sensitive. No other tetracycline—or analogue—can assure you of quicker or more effective antibiotic action. After all, isn't that what you want for your patient?

ACHROMYCIN was a pioneer in tetracycline therapy. Seventeen years of experience have shown that when the respiratory system, the genitourinary system, or the skin and soft tissue require treatment for infection probably caused by any of a number of sensitive strains, ACHROMYCIN is a wise choice for therapy while awaiting test results.

Available in 31 useful forms to meet your situational needs.

Poliomyelitis*

The Bulbar Type

HAROLD H. NORAN, M.D.
Minneapolis, Minnesota

THIS CONDITION actually should be termed the brain-stem type of poliomyelitis since essentially all of the cranial nerves may be involved in various combinations. Involvement of III, IV, V, VI, VII, VIII cranial nerve nuclei is termed the upper cranial nerve type while that of the IX, X, XI and XII is referred to as the lower cranial nerve nuclei type of bulbar poliomyelitis. Actually, any combinations may occur. Involvement of the lower cranial nerve nuclei are the more serious and more important clinically and constitute a typical bulbar palsy.

Poliomyelitis is caused by a filterable virus of three different subtypes. All may produce an acute bulbar palsy. The frequency of the bulbar type of paralytic disease varies from six to 25 percent, but in those with previous tonsillo-adenoidectomies the frequency definitely increases and some bulbar involvement is said to occur in as high as 85 percent of these cases. Pure bulbar involvement is more common in children. In adults there is frequently some associated spinal paralysis.

Pathology

Cranial Nerve Nuclei

The pathological changes are seen primarily in the cranial nerve nuclei and particularly their motor components. This is very similar to the distribution in the spinal cord; however, the sensory nuclei, especially those of the 8th nerve, may also be involved. Cellular inflammatory changes and nerve cell injury and destruction occur. Phagocytic activity takes place as well as vascular congestion and occasionally petechial hemorrhages.

Leptomeninges

A patchy inflammatory change is seen in the leptomeninges. The reticular formation of the medulla frequently shows severe destruction or necrotizing involvement. In the 1946 epidemic A. B. Baker and his associates found this frequently related to the hypoxia and possibly

*Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.

even caused by hypoxia. In other cases it correlated well with autonomic clinical manifestations in the form of respiratory and circulatory disturbances.

Cerebral Hemispheres

The cerebral hemispheres may also be involved and occasionally produce a clinical encephalitis. The motor cortex and particularly the large motor cells are the most frequently involved. The basal nuclei of the hypothalamus may also show involvement. A cerebellar type has been described but has not been well documented pathologically.

Clinical Features

Prodromal Illness

Many cases are preceded by a prodromal illness, usually manifested by influenzal, upper respiratory or gastrointestinal infectious manifestations. There is frequently a short febrile period associated with the prodromal period. The temperature may drop to normal and then within a day or two recur, with the involvement of the central nervous system.

Neurological Involvement

The neurological involvement of the brain stem may be the first manifestation without any prodromal symptoms in a number of cases. Generally, however, there is some elevation of temperature at the time of onset.

Laboratory Findings

The spinal fluid usually shows an increased cell count at the onset. Early the cells are mainly polymorphonuclear but soon become lymphocytes or mononuclears. Twenty-five to 500 cells are common, but occasionally as many as 1,000 to 2,000 may be seen. After a week or so the cell count begins to drop and the protein content increases. The elevation of protein is usually mild to moderate but occasionally may be quite high, causing some concern about the existence of an albuminocytologic dissociation of the Guillain-Barre syndrome. Without abnormality of the cerebral spinal fluid a diagnosis of paralytic or bulbar poliomyelitis is uncertain and said to occur in only 0.5 percent of the cases.

Types of Bulbar Polio

In order to understand the various manifestations of bulbar poliomyelitis one must be familiar with the various clinical types that may occur in relatively pure form or in various combinations.

Cranial Nerve Palsy

The cranial nerve palsy group may involve either the upper or the lower cranial nerves. Marked *ocular palsies* may occur along with ptosis and various pupillary changes; or isolated ocular muscles may be paralyzed. A *Horner's syndrome* is not uncommon. There may be mild or severe paralysis of the muscles of mastication and rarely trismus caused by spasm of these muscles. The *jaw may deviate* to one side or chewing may be impossible with the mouth hanging open. Frequently the weakness can be elicited only by actual testing Some degree of *facial paralysis* occurs in about 50 percent of the cases. This is frequently unilateral but may be bilateral and may involve either predominantly the upper or lower face or the entire face. Deafness and vertigo result from involvement of the cochlear or vestibular nuclei. Vagus involvement is frequent due to involvement of the nucleus ambiguus. This causes *weakness of the palate,* pharynx and vocal cords. The palate may be flaccid or may deviate to one side. A *nasal twang* in the voice is noted. Paralysis of the pharynx causes difficulty in swallowing or inability to swallow and a pooling of secretions. Paralysis of the vocal cords causes difficulty in respiration and aspiration of secretions. Occasionally actual *laryngeal spasm* occurs. There may be inspiratory stridor. Weakness of the tongue is not uncommon and may be unilateral or bilateral and severe.

Respiratory Center

The bulbar respiratory center group may show a *variation in the depth and rate of respirations.* Later prolonged intervals between respirations develop. There is associated anxiety, restlessness, and tachycardia. Increasing periods of apnea develop. Soon there may be confusion, delirium and pulmonary congestion with ultimate cyanosis. Apnea becomes severe and hemorrhagic pneumonia is apt to occur.

Circulatory Center

The bulbar circulatory center involvement is characterized by a deep cherry-red color of the lips and a dusky-red florid, flushed appearance

of the skin. The pulse becomes very rapid, irregular and thready. The blood pressure may be elevated or low. The most consistent finding is *marked decrease in the pulse pressure*. Shock may soon follow with a falling blood pressure. The skin may become cold and clammy with a mottled cyanosis. Hyperthermia, delirium and coma are very serious signs.

Encephalitic Group

The bulbar encephalitic group is characterized by apprehension, anxiety and fear of death. The patient may become hypomanic with a flight of ideas and restlessness. *Disorientation may be prominent and insomnia may be most disturbing.* The encephalitis symptoms are difficult to differentiate from those of hypoxia. Restoration of adequate oxygenation and an adequate airway may result in an improvement or disappearance of the encephalitic symptoms, establishing their hypoxic nature. A true encephalitis involvement no doubt occurs but is rare. Involvement of the hypothalamus may result in hyperthermia, hypertension, gastric hemorrhage and severe gastric or intestinal dilatation. It should be remembered that a severe, acute dilatation of the stomach may cause elevation of the diaphragms and further embarrassment of respiration. Focal encephalitis involvement has been reported but is rare. Twitchings, myoclonic jerkings, tremors and convulsive seizures are rarely encountered. Visual verbal agnosia* has been reported. Spastic hemiparesis, unilateral ataxia, and hydrocephalus have also been reported but are poorly documented by pathological studies.

Cervical Cord Group

The bulbar cervical cord group may show any of the above types in various combinations, but in addition may show paralysis of the diaphragm, intercostal muscles and arms.

Course of Bulbar Polio

The course of bulbar poliomyelitis is frequently acute, generally reaching its peak within a period of several days to a week or so. Fever may be present for several days and drop to normal while the bulbar paralysis and involvement is still progressing.

Recovery

In the non-fatal cases improvement starts to occur generally by the second week and may continue for a rather long period. Before the advent of modern medical and respiratory therapy the mortality was extremely high. With the use of tracheotomy, intubation and artificial respiration and careful neurological and medical care the mortality has been dramatically reduced. Complete recovery has occurred in many cases, and severe residuals necessitating permanent respiratory assistance have been rare. Vital capacity has occasionally remained somewhat reduced, but often not past the point where a useful existence has resulted.

Hypoxia

Hypoxia is the most frequent and probably the most important complication of bulbar poliomyelitis. It may result in many ways. The secretions frequently obstruct the airway. The rare occurrence of trismus may make the handling of secretions difficult, and paralysis of the tongue may also contribute to obstruction of the airway. Laryngeal obstruction may result from paralysis of the vocal cords or reflex spasm of the glottis. Hypoxia may result from pulmonary edema or pneumonia. Circulatory failure may be an important causative factor. Acute gastric dilatation may cause abnormal elevation of the diaphragm, and gastric hemorrhage may lead to anemic anoxia. Hypoxia recurring from respiratory-center involvement is of very serious importance. The patient may aspirate vomitus and be unable to clear the airway because of an inability to cough. Interstitial myocarditis appears in many cases but usually disappears upon recovery.

Electrolyte Imbalance

Disturbances in water and electrolyte balance are common, especially in those receiving artificial respiration. Respiratory alkalosis or acidosis may occur. Renal infection and renal calculi also occur, as do thrombophlebitis and pressure sores.

Differential Diagnosis

This relatively common neurological disease fortunately has now become a clinical rarity, no doubt from the wide-spread use of vaccination. It still must be kept in mind, however, in any

*See Test Your Word Score Page 1213.

acute brain-stem involvement, especially when associated with fever. Differential diagnosis is generally not difficult and can usually be made without confirmatory viral studies. The latter, however, should be carried out.

Guillain-Barre Disease

The fever, the occasional prodromal symptoms, headache, leukocytosis, high sedimentation rate, meningeal signs, and spinal fluid pleocytosis easily differentiate this condition from the bulbar form of the Guillain-Barre disease.

Amyotrophic Lateral Sclerosis

Bulbar amyotrophic lateral sclerosis generally has a slower and more chronic onset and course, usually with a normal cerebral spinal fluid.

Other Diseases

Brain-stem strokes or vascular accidents generally occur in older individuals and frequently have long tract findings. Tumors of the brain stem have a slower onset and slower course and are generally associated with pyramidal tract findings. The rare bulbar form of myasthenia gravis must be differentiated; but again this condition should be associated with a normal spinal fluid examination and an absence of signs of infection. A tensilon test may be helpful, and the electromyogram may make the differential in doubtful cases. Confusion with other viral involvements of the nervous system may occur and at times may necessitate special viral studies for diagnosis. Therapy, however, is much the same. All such cases should be considered as neurological and therapeutic emergencies.

Treatment

There is no specific therapy for the virus, and immune globulin has never proven to be of any value.

Tracheotomy

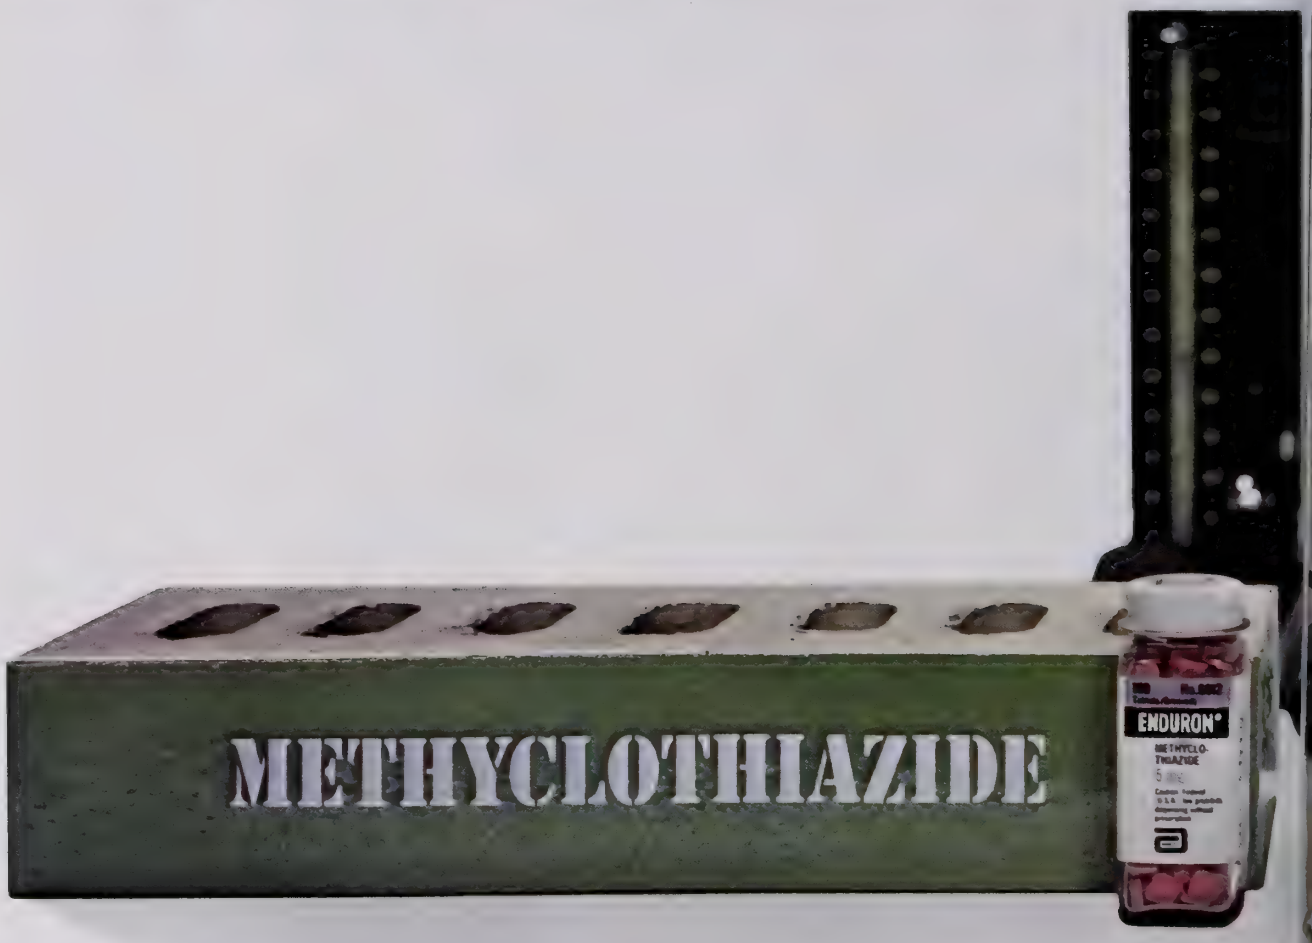
Signs of airway obstruction should always be kept in mind, and early tracheotomy has been proven to be life-saving and the one main factor in altering the mortality. Probably in all cases the Ph of the blood pCO_2, the pO_2, together with measurements of ventilatory gas volumes, should be routinely performed. Artificial respiration is probably best carried out with the positive pressure respirator. Because of the short duration of the illness in some cases there is argument in favor of the nasotracheal tube. Dr. Daly felt this method could be used for as long as a period of ten days. Some anesthesiologists feel there is some danger in using it for a period longer than three or four days.

Good Nursing

Good nursing care, of course, is extremely important. Nutrition and hydration must be maintained, first by intravenous feedings and then by nasal gastric tube feedings. Scrupulous cleansing of respirators reduces the incidence of complicating pneumonia. There is no uniform agreement as to whether prophylactic antibiotics should be used.

Many problems may be encountered, taxing the ingenuity of the physician. There may be adequate oxygenation but poor elimination of carbon dioxide. Cyanosis is an unreliable guide to inadequate oxygenation. With hypoventilation oxygen may cause the patient to remain pink with a greatly reduced volume exchange. Oxygen should be used as an adjunct to, rather than a substitute or support for respiratory volume. Circulatory failure may lead to poor perfusion and resultant inadequate ventilation.

Once the patient has been started on artificial respiration constant nursing and medical supervision are necessary. Patients requiring this type of therapy are in constant danger of complications. Frequent examinations and observations are mandatory to detect and treat the resulting complications. The anesthesiologist and the internist may be very helpful consultants to the neurologist in the care of the patient seriously ill with bulbar poliomyelitis.



Neither man nor woman can be worth anything until they have discovered that they are fools. This is the first step toward becoming either estimable or agreeable; and until it is taken there is no hope.—Melbourne

Abbott Antihypertensive Building Blocks

A simplified approach to the practical management of hypertension

Enduron: (methyclothiazide) A basic building block for mild hypertensives

Excellent day-long Na^+ output, yet easy on the K^+

Enduron provides an excellent starting therapy. Your patient's sodium excretion is greatly enhanced. Yet potassium loss is low.

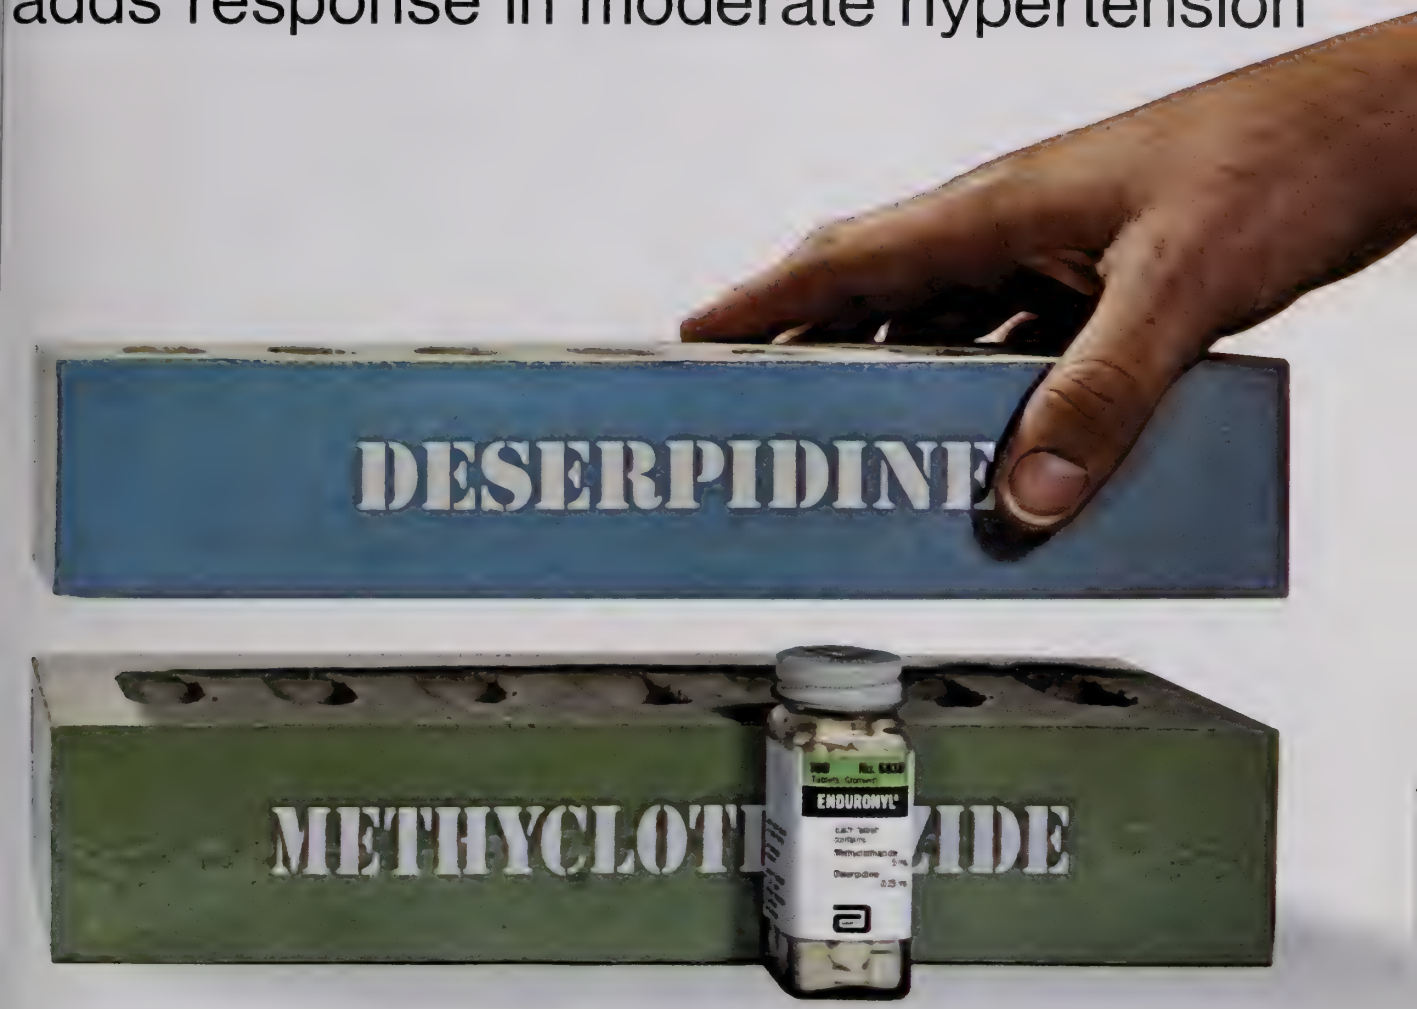
The therapeutic action is smooth, and persists for a full 24 hours. With Enduron you can prescribe convenient once-a-day dosage without skimping your patients on day-long thiazide effectiveness.

Of course, as with all thiazides, supplemental dietary potassium should also be considered.

Use Enduron as a basic therapy in patients with mild to moderate hypertension. A single 5-mg. tablet each day is ample in most cases.

Once a day, every day

ENDURON®



METHYCLOTHIAZIDE

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

Enduronyl: Its deserpidine component adds response in moderate hypertension

Less frequent rauwolfia side effects than with reserpine

When you wish to build further response, consider shifting to Enduronyl.

Enduronyl adds a building block of *deserpidine*. This is a purified rauwolfia alkaloid available only from Abbott. It adds good antihypertensive and tranquilizing activity. Yet its incidence of untoward effects, particularly lethargy and depression, is lower than with reserpine.

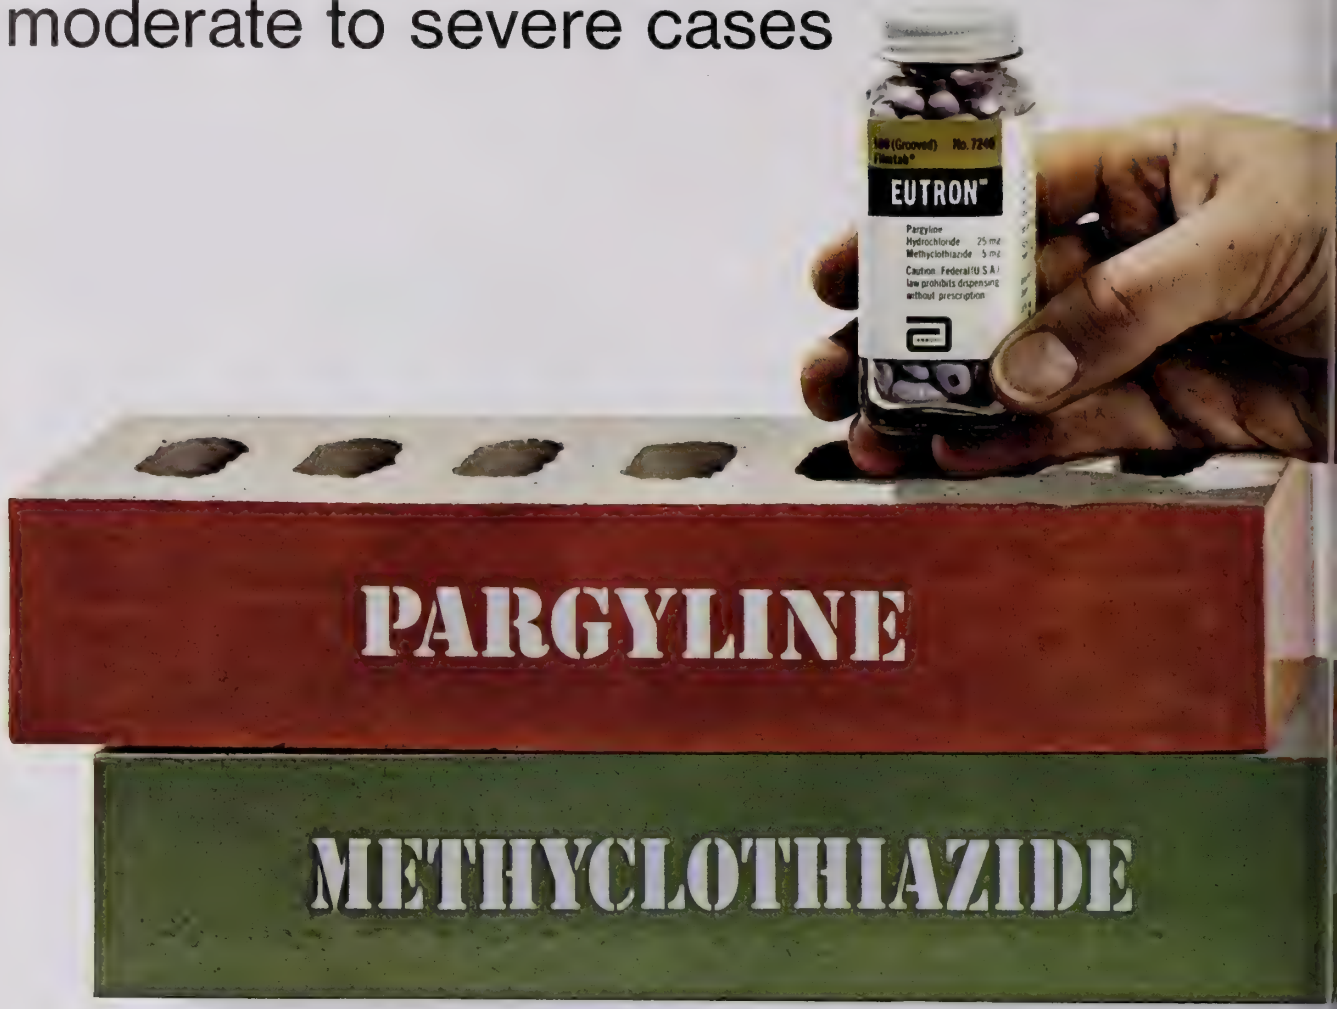
Enduronyl is available plain or Forte. The latter provides its variation where most helpful, by doubling the deserpidine.

Use Enduronyl for patients throughout the broad range of mild to moderately severe hypertension.

Once a day, every day

ENDURONYL®

METHYCLOTHIAZIDE 5 mg. with DESERPIDINE 0.25 mg. or (FORTE) 0.5 mg.



MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

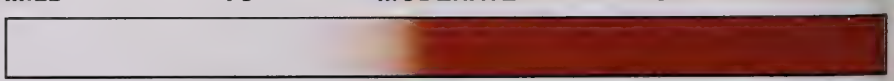
Eutron: A unique combination for handling moderate to severe cases

Affords almost uniform diastolic reduction in all body positions

Eutron lowers diastolic pressures nearly equally, whether your patient is standing up or lying down.

Thus, in clinical trials, average *standing* diastolic readings were reduced from 112 pre-treatment to 90 post-treatment; *sitting* from 115 to 95; and *recumbent* from 112 to 94.

Note that following Eutron, the diastolic reductions were nearly alike in all three body positions.



Use Eutron for managing your moderate to severe cases. Its building blocks enhance each other; hence lesser doses often suffice.

Once a day, every day

EUTRON™

PARGYLINE HYDROCHLORIDE 25 mg.
with METHYCLOTHIAZIDE 5 mg.

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

ENDURON® | ENDURONYL®

METHYCLOTHIAZIDE

Each tablet contains
Methyclothiazide 5 mg. with
Deserpidine 0.25 mg. or 0.5 mg.

Indications: Edema and mild to moderate hypertension (Enduron), and mild to moderately severe hypertension (Enduronyl). More potent agents, if added, can be given at reduced dosage.

Contraindications: Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease or impending hepatic coma (hepatic coma due to hypokalemia has been reported in patients on thiazides). Do not use Enduronyl in severe mental depression, suicidal tendencies, active peptic ulcer, or ulcerative colitis.

Warnings: Consider possible sensitivity where there is history of allergy or asthma. If added potassium is indicated, dietary supplementation is recommended. Reserve enteric-coated potassium tablets for cautious use only when necessary, as they may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation often requiring surgery; discontinue them immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occurs. Neither Enduron nor Enduronyl contains added potassium.

Precautions: Use thiazides cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery, thiazides may reduce response to vasopressors, and increase response to tubocurarine. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia) in all patients. In hypokalemia (especially in digitalized patients) give supplemental potassium. In hypochloremic alkalosis, give supplemental chloride.

Use rauwolfias with caution in patients with history of peptic ulcer. Rauwolfias with anesthetics may produce hypotension and bradycardia. Discontinue Enduronyl two weeks before elective surgery. Consider vagal blocking agents during emergency surgery. In epilepsy, adjust anticonvulsant dosage. In electroshock, shorten stimulus strength and duration. In occasional patients with depressive tendencies, rauwolfias may precipitate severe mental depression that usually disappears when drug is stopped.

Adverse Reactions: Thiazide reaction include blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, serum uric acid or blood sugar; anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, symtomatic gout, and pancreatitis. Cutaneous vasculitis in the elderly has been reported with other thiazides. Adverse effects with deserpidine are qualitatively similar to those with reserpine, but their incidence is lower. These include nasal stuffiness, abdominal cramps or diarrhea, nausea, headache, weight gain, reduced libido and potency, peptic ulcer aggravation, epistaxis, skin eruption, asthma in susceptible patients, electrolyte imbalance, excessive salivation, and a reversible Parkinson's syndrome. Excessive drowsiness, fatigue, weakness, and nightmares may signal mental depression. Thrombocytopenia, purpura, and a symptom manifested by dull sensorium, deafness, uveitis, glaucoma, and optic atrophy are rare allergic reactions to other rauwolfias. Hypotension from antihypertensive agents may precipitate angina attacks in susceptible individuals. Usually adverse reactions disappear when drug is withdrawn.

EUTRON™

Each tablet contains
Pargyline Hydrochloride 25 mg.
with Methyclothiazide 5 mg.

Indications—Moderate to severe hypertension.

Contraindications—Pheochromocytoma, paranoid schizophrenia, hyperthyroidism and advanced renal failure. Not recommended in malignant hypertension, children under 12, pregnant patients.

Do not use with: centrally or peripherally acting sympathomimetic drugs; foods high in tyramine (e.g., aged and natural cheeses); parenteral reserpine or guanethidine; imipramine, amitriptyline, desipramine, nortriptyline or their analogues; other monoamine oxidase inhibitors; methyldopa or dopamine; separate Eutron and these agents by two weeks.

Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease; impending hepatic coma from thiazide-induced hypokalemia.

Warnings—Patients: 1. No other drugs (particularly "cold preparations" and antihistamines), cheese or alcohol without physician's consent. 2. Promptly report orthostatic symptoms, severe headache, other unusual symptoms. 3. Angina pectoris or coronary artery disease patients must not increase physical activity with improved anginal symptoms or well-being.

Physicians: 1. Use antihistamines, hypnotics, sedatives, tranquilizers and narcotics (meperidine contraindicated) cautiously in reduced doses. 2. Stop Eutron two or more weeks before elective surgery; in emergency surgery reduce premedication (narcotics, sedatives, analgesics, etc.) to 1/4 to 1/5; carefully adjust anesthetic dosage to patient response. 3. Use cautiously in advanced renal failure. 4. Pargyline may induce hypoglycemia. 5. Consider possible sensitivity reactions when a history of allergy or asthma is present. 6. If potassium is indicated, dietary supplement is recommended; enteric-coated potassium tablets may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation frequently requiring surgery; discontinue medication immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occurs; Eutron does not contain added potassium. 7. Possible systemic lupus erythematosus has been reported for thiazides.

Precautions—Pargyline: Use cautiously at reduced dosage: caffeine, alcohol, antihistamines, barbiturates, chloral hydrate, other hypnotics, sedatives, tranquilizers, narcotics. Periodically do urinalyses, blood counts, liver function tests, etc. Use with caution in liver disease. Watch for orthostatic hypotension, especially in impaired circulation (e.g., angina pectoris, coronary artery disease, cerebral arteriosclerosis); also, augmented hypotension in concomitant febrile illnesses. Reduce or discontinue if hypotension is severe. In impaired renal function watch for cumulative drug effects, elevated BUN and other evidence of progressive renal failure; withdraw drug if these persist. In surgery increased central depressant response (hypotension and increased sedative effect) can be controlled by (1) discontinuing at least two weeks prior; (2) in emergency surgery lowering dose of premedication; (3) when necessary, administering a vasopressor. Do not use in hyperactive and hyperexcitable patients. Pargyline may unmask severe psychotic symptoms where emotional problems pre-exist. Use cautiously in Parkinsonism, especially with antiparkinsonian agents. In prolonged therapy, examine for change in color perception, visual fields, fundi and visual acuity. Also, prolonged therapy has made certain patients refractory to nerve blocking effects of local anesthetics.

Methyclothiazide: Use cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery thiazide may reduce vasopressor response and increase tubocurarine response. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia). Give supplemental chloride if hypochloremic alkalosis occurs and supplemental potassium if hypokalemia occurs (especially in digitalized patients). Thiazides may decrease serum P.B.I. without signs of thyroid disturbance.

Adverse Reactions — Pargyline: Orthostatic hypotension and associated symptoms, mild constipation, fluid retention, edema, dry mouth, sweating, increased appetite, arthralgia, nausea, vomiting, headache, insomnia, difficult in micturition, nightmares, impotence, delayed ejaculation, rash, purpura, weight gain, hyperexcitability, increased neuromuscular activity and other extrapyramidal symptoms. Drug fever is extremely rare. Reduction in blood sugar and hypoglycemic effects are possible. Congestive heart failure has been reported in a few patients with reduced cardiac reserve.

Methyclothiazide: Blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, blood sugar or serum uric acid (gout may be induced); anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice and pancreatitis. Cutaneous vasculitis in elderly patients has been reported with other thiazides.

If side effects are severe or persist, reduce dosage or withdraw drug. 804438R

Clinical Reviews

A program of lectures and discussions on problems of general interest in medicine and surgery will be presented at the Mayo Clinic and Mayo Foundation, Rochester, Minnesota. Identical sessions are offered on October 28, 29 and 30 and November 11, 12 and 13.

This program is acceptable for credit by the American Academy of General Practice and the College of General Practice of Canada. The registration fee for this program is $20.

The number of physicians who can be accommodated is necessarily limited. For this reason identical programs will be offered two successive weeks. The program will be presented first on October 28, 29 and 30 and repeated on November 11, 12 and 13. Those wishing to attend should communicate with M. G. Brataas, Mayo Clinic, Rochester, Minnesota 55901, indicating which session they would prefer to attend.

A Program of Clinical Experience in Outpatient Education for Control of Diabetes Mellitus

The Diabetes Detection and Education Center, 916 East 15th Street, Minneapolis, Minnesota, has developed a program of medical and paramedical education for physicians, nurses, public health personnel, and dietitians. The course includes five days of intensive instruction in the medical, nursing and dietetic team approach to management of diabetes mellitus in the outpatient. The purpose of the course is to develop maximum skills in medical and paramedical personnel so that patients may receive optimum care, and physicians may be relieved of time consuming, intensive instruction of the patient with diabetes. Classes are scheduled for the weeks of: July 22, August 5, August 26, September 9, September 23, October 7, October 28, November 4, November 18, December 2, December 16, and December 30. Rooms and meals are available at the Center at minimum cost.

For further information, contact D. D. Etzwiler, M.D., or C. B. Cohen, M.D., at the above address.

National "Outstanding Service" Award Given Minnesota Physicians Planning Service Corporation Organization

The Minnesota office of Physicians Planning Service Corporation, a Nationwide medical service organization, has been named that organization's "outstanding service office in 1967."

The award to James J. Krakowski, CLU, and his associates, 406 Pioneer Building, St. Paul, was made at a recent meeting in New York on behalf of the 50,000 physicians who are serviced by PPSC.

Presenting an inscribed clock to Mr. Krakowski to commemorate the honor were Dr. Edward R. Annis, a past president of the American Medical Association, and Dr. Edwin Dunlop, director of research at the Fuller Sanitarium, South Attleboro, Mass. Both Drs. Annis and Dunlop are trustees of the National Association of Residents and Interns and the American Professional Practice Association. NARI, APPA and the Phi Delta Epsilon fraternity are medical organizations for whose members Physicians Planning Service Corp administer a wide range of socio-economic benefits. The award received by Krakowski was the top service citation for agencies serving these members of the medical profession.

Optic Neuritis*

JAMES A. MORIARTY, M.D.†
Minneapolis, Minnesota

OPTIC NEURITIS may be classified as to location of the lesion in the optic nerve. Those neuritic lesions involving the optic nerve which are visible upon funduscopic examination are described by Walsh as intraocular. Lesions posterior to the eye are retrobulbar; those peripheral to the optic nerve are perineuritic.

Retrobulbar neuritis is a term which usually indicates involvement of the papillomacular bundle of the optic nerve in its orbital or intracranial course. Ronne included any level of the optic nerve from the orbit to the lateral geniculate body.

The involvement of the optic nerve in optic neuritis is the result of inflammation, demyelinization or degeneration.[1]

Symptoms and Signs

The intraocular optic neuritis, often called papillitis, has a sudden onset with marked visual loss and is usually unilateral. *There is associated eye pain, pain with movement of the eye, and headache.*

Children with optic neuritis experience spontaneous pain in the involved eye, pain on movement of the eye, and tenderness to palpation, as adults do. Children have a headache more frequently than adults; however, there is a greater tendency to simultaneous bilateral involvement and greater frequency of papillitis than retrobulbar neuritis.[13]

The funduscopic examination is primarily one of congestion, infiltration, exudation. The veins are dilated and the arteries narrowed. Elevation of the disc is limited, the margins are blurred and there may be hemorrhages. Exudate occurs over the disc and the retina. Twenty-three percent of Carroll's[2] patients complained of head pain, usually on the same side as the optic neuritis and located above and behind the eye. More frequently than not the pain developed before the visual loss—usually

*Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.

†Assistant Professor, Division of Neurology, University of Minnesota Hospitals.

a day or two preceding, but sometimes even two to four weeks before visual impairment. Tenderness to palpation of the globe occurred in 16 percent.

Optic Neuritis vs. Papilledema

Ophthalmoscopically optic neuritis cannot be differentiated from papilledema on a single examination. Papilledema usually has constriction of the peripheral fields. The peripheral field of optic neuritis is generally unrestricted to a large test object. Whereas the blind spot is enlarged in papilledema, optic neuritis has a central field defect; color vision defect often persists and concentric constriction of the central isotopes is present.

Papilledema can most readily be identified when one or more of the following changes have intensified: hyperemia of the disc, blurred disc margin, venous engorgement with loss of pulsation, loss of physiological cupping, and protrusion of the disc. Frequent and repeated funduscopic examination reveals progression in these features of papilledema, whereas none of these alone is sufficient to diagnose papilledema.

Etiology

In Adults

One third of Carroll's series of 240 cases of optic neuritis had demyelinating disease diagnosed as multiple sclerosis. One third had spontaneous occurrence of the optic neuritis and one third, a variety of associated diseases, including diseases of the adjacent structures, infectious diseases, non-infectious conditions, toxic agents, Leber's hereditary disorder, and vascular disease.

An unusual toxic etiology[3] of optic neuritis caused by the monoamine oxidaze inhibitor pheniprazine (Catron) caused three similar cases. The patients used pheniprazine for one month. There was marked impairment in the color vision. Later the visual acuity was moderately lowered. In most cases full recovery is seen after withdrawal of the drug.

Cataract extraction may result in optic neuritis.[4]

In Children

No cause could be determined in 53% of the 41 patients studied by Kennedy and Carroll.[13] Half of the children with undetermined cause of the optic neuritis had some infection immediately preceding or concomitantly with the attack of optic neuritis. Usually the infection was an upper respiratory tract infection.

Twenty-seven percent of the children had optic neuritis associated with familial or generalized disease. These conditions included diabetes, malnutrition, measles, congenital syphilis and a hereditary disorder called Leber's disease.

About 20% of the children with optic neuritis had associated multiple sclerosis in a mean follow-up time of eight years.[14]

Diagnosis

With a diagnosis of expected retrobulbar neuritis, investigation includes a complete neurological examination, lumbar puncture, skull x-rays, electroencephalogram, a brain scan using technetium 99m and, when indicated, contrast studies including cerebral angiography and/or pneumoencephalography.

Differential Diagnosis

The differential diagnosis of optic neuritis includes a wide range of treatable and untreatable conditions. The arteritis and mass lesions which produce optic neuritis lend themselves to therapeutic benefit after the diagnosis has been made. Treatment may be of benefit in the hereditary degenerative types of involvement.

Mass Lesion

There is a real danger of mistaking an intracranial process for retrobulbar neuritis. Central defects of the visual field may arise. Chamlin found no normal peripheral fields in 33 cases of intracranial mass lesions with central scotoma.

In ruling out intracranial tumors which can present with scotomata, the neurological examination may show focal signs and symptoms

TABLE I

Proportion of Patients in Treated and Control Groups with Normal Vision on Entry and at Days 1, 8, 15, 22, and 30.

Day of trial	Proportion (%) with Normal Vision	
	Corticotrophin	Control
1	4%	8%
8	56%	12%
15	76%	20%
22	80%	30%
30	92%	52%

and signs of progressive involvement. The skull x-ray is viewed for erosion of the sella, the sinuses or the sphenoid ridge. A cerebral spinal fluid protein may be elevated. Slow wave or spike abnormality on the electroencephalogram may be helpful in detecting a neoplasm.[5]

Ninety-five percent of the meningiomas scanned using technetium 99m gave positive results.[6] Small tumors near the chiasm and dorsum sella were the only ones likely to be missed on brain scan technique.

The chiasmal lesion gives rise to a clockwise progressive field defect in the left eye and a counter-clockwise progressing field defect in the right eye. Both begin with a superior temporal field defect.

Ischemic Optic Neuritis

Ischemic optic neuritis results in acute visual failure, as does optic neuritis from other causes. Pallor results with or without edema. Retinal vessels may be attenuated. There is a minimum of funduscopic findings.

The basic lesion is a *progressive occlusive process affecting the ophthalmic artery* in its branches to the optic nerve, retina, and extra ocular muscles. Thrombosis is not a constant histological feature in ischemic optic neuritis when giant cell arteritis is seen. It is likely that intimal proliferation is the main cause of reduction in size of the arterial lumen, resulting in ischemia of the optic nerve.[7] Blindness probably results from failure of the circulation in the optic nerve due to extensive involvement of the short and posterior ciliary arteries around the optic nerve head. Ischemic optic neuritis or infarction of the optic nerve is probably the commonest cause of visual loss in giant cell arteritis, although central retinal artery occlusion has been demonstrated ophthalmoscopically and histologically. MacFaul recommends a consideration of *giant cell arteritis* in the differential diagnosis of optic nerve ischemia in elderly people.

The differential features of ischemic optic neuropathy and optic neuritis were outlined by C. J. Earl[8] (Table 2).

Temporal Arteritis

In 1962 Simonds and Cogan designated a syndrome called temporal arteritis, the classical symptoms of which are absent or present only after the ocular phase of the disease. The patient may have only a history of vague headaches, general malaise, loss of weight and anorexia. Tenderness and swelling of the temporal artery may be absent or minimal.

The disorder presents as a quiet ischemic blindness in one eye, followed by a similar occurrence in the second eye after an interval of days or weeks.

Temporal artery biopsy may be positive despite the absence of classical symptoms in this region. The erythrocyte sedimentation rate may be increased.

A common cause of blindness in the elderly is occult temporal arteritis.

Of the 46 patients studied by Cullen[9] with the typical picture of central retinal artery occlusion, six were proven to have temporal arteritis by temporal artery biopsy. The typical picture consisted of arterial spasm, or obliteration with edema of the retina and a cherry-red spot.

Of the 20 patients with ischemic optic neuritis, 11 were proven to have temporal arteritis by temporal artery biopsy. These cases showed an acute visual failure, usually complete or nearly so, inactive or sluggish pupils, more often than not pale edematous disc or pallor without edema, a few hemorrhages on the disc, and retinal vessel attenuation.[9]

TABLE 2

	Ischemic Optic Neuropathy	vs.	Optic Neuritis
Onset	A more sudden onset		A less sudden onset
Pain	Pain on movement of eye is uncommon		Pain upon movement of eye is common
Disc appearance	Swollen but grey disc		Hyperemic and swollen
Appearance of veins	Retinal arterioles narrowed		No narrowing
Visual loss	Complete blindness in one or both eyes in 30% of cases		Central or paracentral scotoma

All patients with ischemic optic neuritis should be presumed to be suffering from occult temporal arteritis until proven otherwise. Cullen found that 50% of his patients with ischemic optic neuritis had temporal arteritis, and that 10% with a central retinal artery occlusion had temporal arteritis.

The treatment of occult temporal arteritis is 40 units of ACTH I.M. b.i.d. pending confirmation of the biopsy, followed in a few days by prednisone, 40 mg. P.O. daily, with reduction of the dosage as the blood sedimentation rate begins to decrease after seven to 10 days of therapy.

Hereditary Optic Atrophy (Leber's disease)

Leber's disease is a relatively acute central visual loss involving both eyes. The clinical picture is one of bilateral retrobulbar neuritis. Onset is from age 15 to 25 years. It occurs usually in males and has sex-linked or recessive hereditary features. Considerable visual impairment is to be expected.

Neuromyelitis Optica (Devick's disease)

Devick's disease is a necrotizing degenerative process which involves both optic nerves with optic neuritis and the spinal cord with a transverse myelitis. Either the optic neuritis or the transverse myelitis may precede the other. There is complete tissue necrosis in the areas involved and cavity formation results. Cerebral symptoms of headache, changes in consciousness, and convulsions occasionally occur. The patient may have either one attack with remission or repeated episodes. Paraplegia and severe visual impairment result.

Pseudo-Papilledema

Pseudo-papilledema is to be differentiated from optic neuritis. Pseudo-papilledema may occur with hyperoptic or astigmatic refractive errors and with Drusen deposits in the disc head. Pseudo-papilledema is sometmies seen congenitally.

Prognosis of Optic Neuritis

The overall prognosis is dependent upon the etiological factor, response to therapy where indicated, the possible development of disseminated sclerosis, and age.

Prognosis in Relationship to Age

The prognosis for vision was better for those patients less than 45 years of age. Average time of recovery of maximal visual acuity was two months, irrespective of age and sex. The fastest recoveries occurred in a sixteen-year-old girl whose vision improved from 6/60 to 6/6 within two weeks, and in a 23-year-old whose vision improved from 6/18 to 6/6 in a similar length of time. Two patients, however, took six months to return to normal vision.

A good recovery was defined as one in which the final corrected visual acuity was 6/9 or better. In the younger age group, less than 45 years of age, three out of 83 (4%) failed to make a good recovery. In the older age group five out of 21 (24%) made little or no recovery. The reason for this difference is unknown, although a relatively poor blood supply in the older patients may be responsible for the poor recovery as well as the increased frequency of a more severe visual acuity loss initially at the onset of the optic neuritis.[12]

Optic Neuritis in Children

The natural course of optic neuritis in children is one of spontaneous recovery. Improvement begins before the end of the third week and reaches a maximum of visual improvement by six months.[13]

Relationship of Retrobulbar Neuritis to Multiple Sclerosis

In evaluating 87 individuals with retrobulbar neuritis over an interval of 10 to 15 years 32% developed disseminated sclerosis.[10] In the younger age group, between 20 and 44, 50% had a chance of developing disseminated sclerosis.[10]

In a mean follow-up time of eight years children who had optic neuritis were less prone to develop multiple sclerosis than the young adult. Eight of 33 children did develop multiple sclerosis.[13]

Visual Field Studies and Optic Nerve Involvement

In the remission phase of multiple sclerosis, depression of the visual field is the most common tangent screen (2 meter) finding. Central or paracentral scotomata plus depression of the visual field is the next most common finding. Central or paracentral scotomata without depression of the visual field was not found in 123 patients in the remission phase.[11]

Thus visual field studies gave a much better indication of the involvement of the optic nerves than the ophthalmoscopic examination. Although one third of Zeller's patients experienced a visual loss at the onset, 74% had visual field changes at some stage of the disease.[11] Detection of the visual field deficit was facilitated by decreasing the level of illumination from seven-foot to four-foot candles.[11]

Treatment

Patients treated with corticotrophin improved more rapidly than the control group who had retrobulbar neuritis in one eye and were not treated. At the end of 30 days of treatment a much higher proportion of the treated group had regained normal vision (using Jaeger scale J1-J2). Forty units of corticotrophin were given daily intramuscularly.

This advantage to the treated group becomes evident at the end of the first week but is most distinct at the end of two weeks.[14]

Rawson noted the rapid relief of eye pain in the corticotrophin-treated group, all of whom experienced relief within a few hours of the first injection and became free of pain within 48 hours. The control group on the other hand often continued to have orbital pain for a period of two weeks. When the visual acuity was lower than the 16 level, the corticotrophin group clearly improved faster.

Shakespeare: Pharmacologia
Mandragora

"Give me to drink mandragora,
That I might sleep out this great gap of time
My Antony is away."*

Thus does Cleopatra address her attendant Charmain, when separated from her lover, Antony.

Mandragora, a soporific and narcotic prominent and popular in medieval European pharmacology, is likewise referred to in "Othello" when the villain Iago says of Othello:

"Not poppy, nor mandragora,
Nor all the dreamy syrups of the world,
Shall ever medicine thee to that sweet sleep,
Which thou ow'dst yesterday."†

Mandragora was a derivative from the mandrake plant, an herb similar to the May apple and one of the potato family.

Share Your Medical Journals With Colleagues Overseas

Through the DOCTOR TO DOCTOR PROGRAM physicians overseas are receiving month by month the current medical journals they have requested. These journals are sent directly to the overseas colleague by the U.S.A. physicians—their own journals after they are read.

In this Program the U.S.A. physician sends direct to a fellow specialist overseas his specialty journal(s); we supply the name and address of the overseas doctor and the subject of the journal desired. From then on it is a liaison strictly between the two—one in the U.S.A. and the other "somewhere overseas."

If you wish to participate, please send the titles of journals (particularly specialty journals) you will mail to colleagues overseas to: Ada Chree Reid, M.D., Director, AMA DOCTOR TO DOCTOR PROGRAM, 10 Columbus Circle-Room 1270, New York, New York 10019.

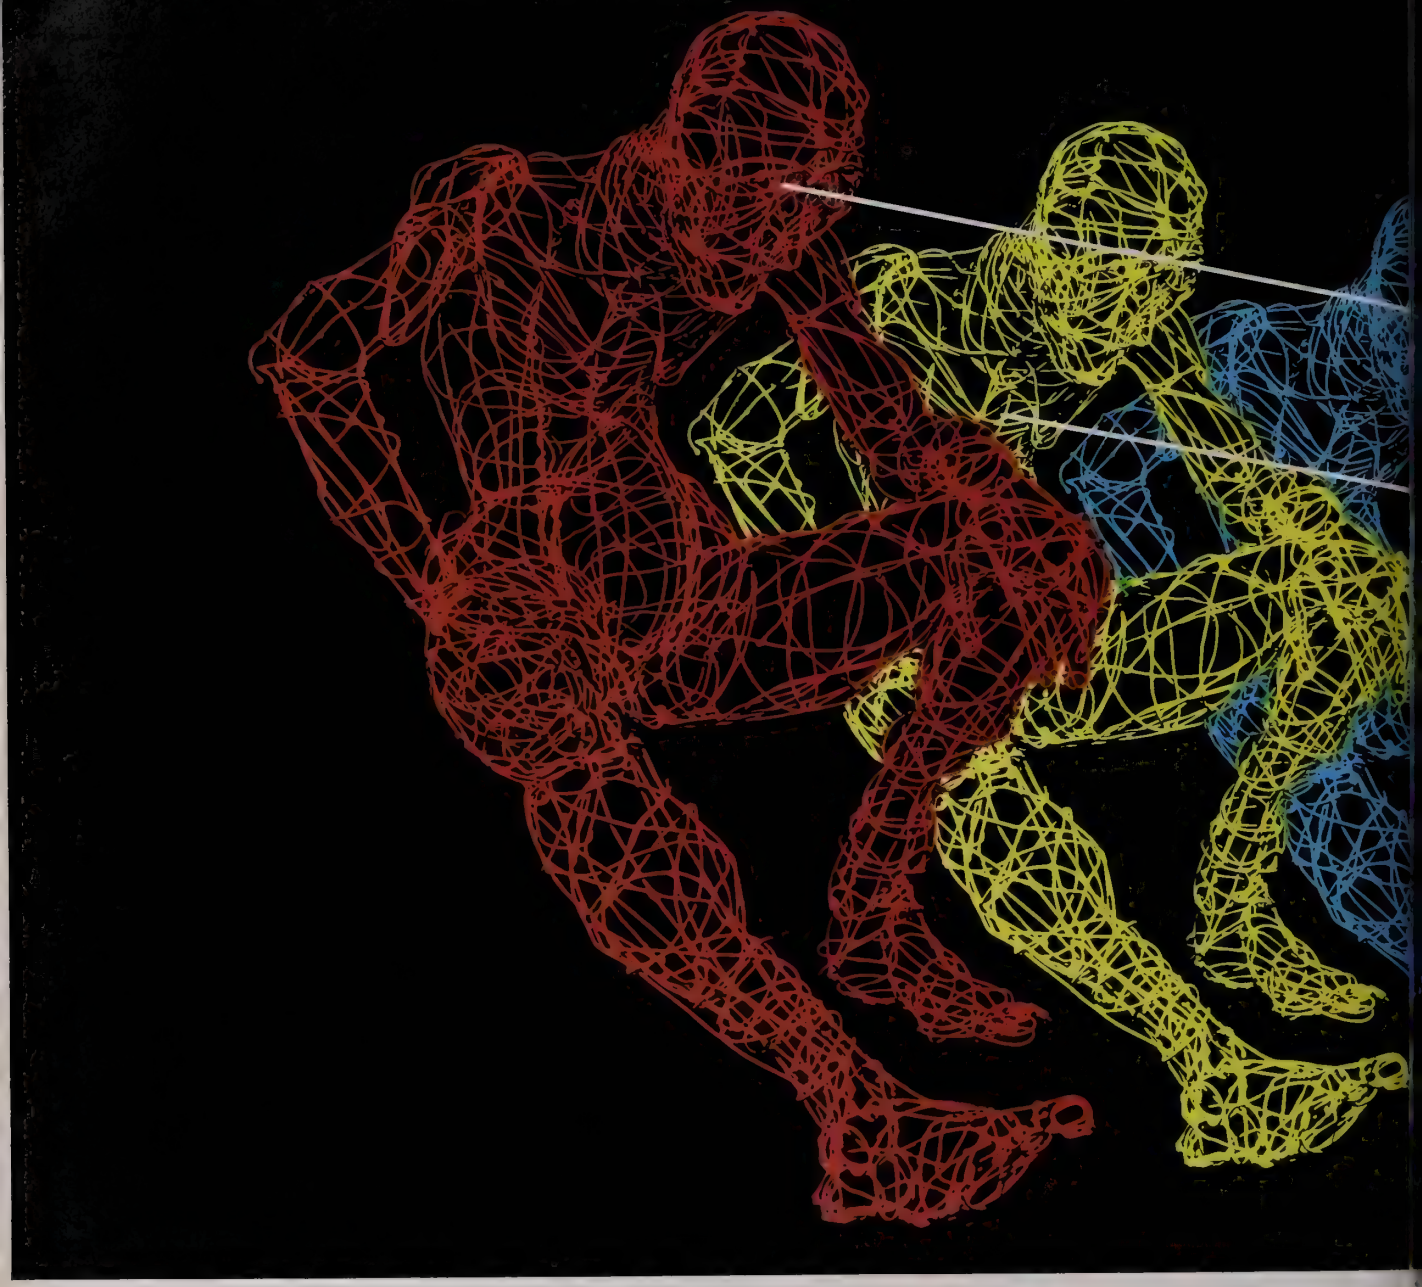
He's had enough excitement for one day.

For the patient who has been through an accident, the worry and anxiety following the experience may actually heighten the perception of pain. This is why there's a classic ¼ grain *sedative* dose of phenobarbital in Phenaphen with Codeine—*to take the nervous "edge" off,* so the rest of the formula can control the pain more effectively.

Phenaphen® with Codeine

Phenaphen® with Codeine No. 2, No. 3, or No. 4 contains: *Phenobarbital* (¼ gr.), 16.2 mg. (Warning: may be habit forming); Aspirin (2½ gr.), 162.0 mg.; Phenacetin (3 gr.), 194.0 mg.; Hyoscyamine sulfate, 0.031 mg.; Codeine Phosphate, ¼ gr. (No. 2), ½ gr. (No. 3), or 1 gr. (No. 4). (Warning: may be habit forming).



THE COMPOUND ANALGESIC THAT CALMS INSTEAD OF CAFFEINATES

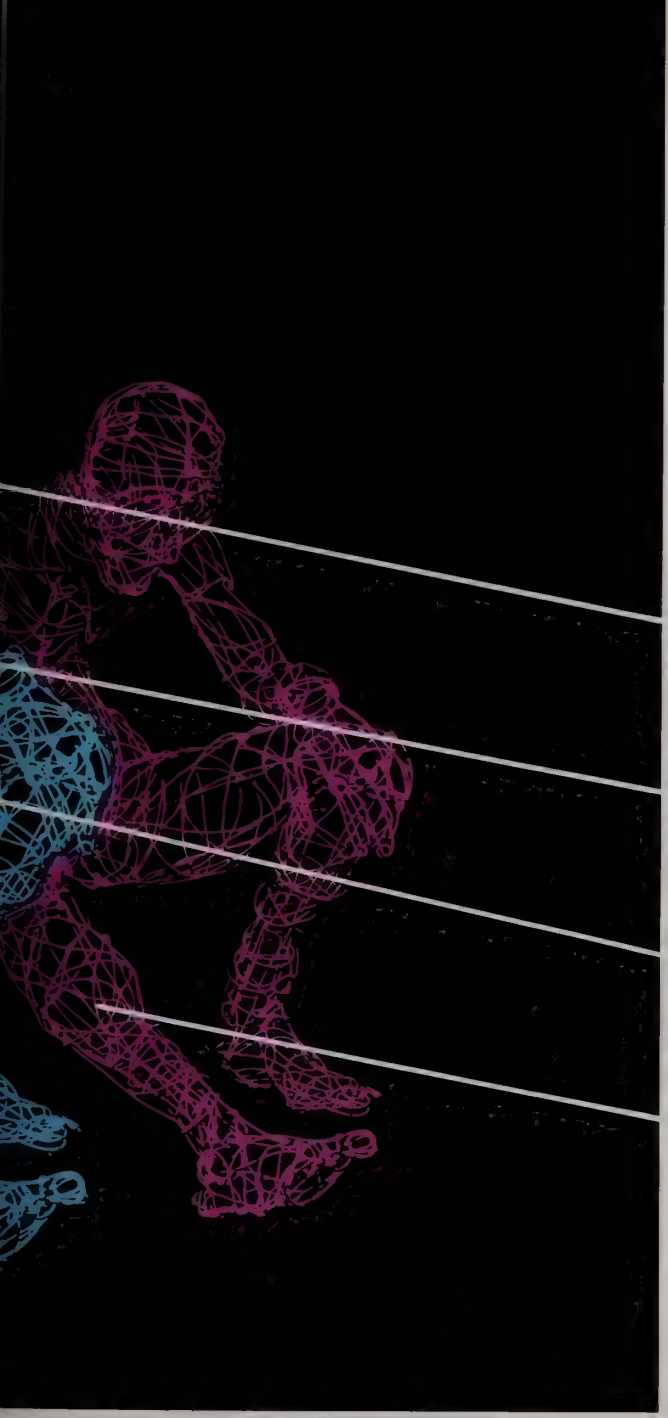
Indications: Phenaphen with Codeine provides relief in severer grades of pain, on low codeine dosage, with minimal possibility of side effects. Its use frequently makes unnecessary the use of addicting narcotics. **Contraindications:** Hypersensitivity to any of the components. **Precautions:** As with all phenacetin-containing products excessive or prolonged use should be avoided. **Side effects:** Side effects are uncommon, although nausea, constipation and drowsiness may occur. **Dosage:** 1 or 2 capsules at 2 to 4 hour intervals, or as directed by physician. For further details see product literature.

A. H. ROBINS COMPANY
RICHMOND, VA. 23220 A·H·ROBINS

a comprehensive hematinic

Description: Each Pulvule® contains—

Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	150 mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin (The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)	7.5 mcg.
Iron, Elemental (as Ferrous Fumarate)	110 mg.
Ascorbic Acid (Vitamin C)	75 mg.
Folic Acid	1 mg.



Indications: Trinsicon® (hematinic concentrate with intrinsic factor, Lilly) is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia.

Contraindications: Hemochromatosis and hemosiderosis.

Precautions: Anemia is a manifestation that requires appropria investigation to determine its cause or causes.

In pernicious anemia, the use of folic acid without adequa vitamin B_{12} therapy may result in hematologic remission but ne rological progression. Adequate doses of vitamin B_{12} (parentera or oral with potent intrinsic factor as in Trinsicon® [hematin concentrate with intrinsic factor, Lilly]) usually prevent, halt, improve the neurological changes.

As with all preparations containing intrinsic factor, resistanc may develop in some cases of pernicious anemia to the potenti tion of absorption of physiological doses of vitamin B_{12}. If resis ance occurs, parenteral therapy, or oral therapy with so-calle massive doses of vitamin B_{12}, may be necessary. No single re men fits all cases, and the status of the patient observed follow-up is the final criterion for adequacy of therapy. Period

You can treat combined deficiencies with

Trinsicon®

—the multifactor hematinic

Vitamin B_{12} plus intrinsic factor (15 mcg. B_{12} activity)—helps provide adequate levels of this important vitamin.

Folic acid (1 mg.)—treats nutritional macrocytic anemias and/or malabsorption syndromes.

Ascorbic acid (75 mg.)—augments the conversion of folic acid to its active form and helps iron absorption.

Iron (110 mg.)—treats hypochromic anemia.

linical and laboratory studies are considered essential and are ecommended.

dverse Reactions: In rare instances, iron in therapeutic doses roduces gastro-intestinal reactions, such as diarrhea or consti- ation. Reducing the dose and administering it with meals will inimize these effects.

In extremely rare instances, skin rash suggesting allergy has llowed oral administration of liver-stomach material. Instances f apparent allergic sensitization have also been reported after ral administration of folic acid.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a tandard response in the average uncomplicated case of perni- ious anemia.)

low Supplied: Pulvules Trinsicon® (hematinic concentrate with ntrinsic factor, Lilly), in bottles of 60 and 500. [032568]

Additional information available to physicians upon request.

Eli Lilly and Company, Indianapolis, Indiana 46206.

ATLAS CHEMICAL INDUSTRIES, INC.

Acute Poisoning*

EDWARD JIMENEZ-PABON, M.D., PH.D.†
Minneapolis, Minnesota

DRUGS OR CHEMICALS become harmful to man if they accumulate rapidly and in abnormal amounts within the body tissues. This state of acute intoxication may develop following accidental, suicidal or criminal exposure to these compounds.

Accidental poisoning may occur at any age, although it is more common in the first five years of life[1] when children frequently put many objects into their mouth. In adults, accidental poisoning results from attempts at self-medication or mistaking one drug for another.

Suicidal poisoning is most common in the late teens and early twenties.[2]

Criminal poisoning is not frequent and presents less of a problem than the preceding two types of intoxication.

Acute intoxication can follow exposure to so many drugs or chemicals that only the most common ones will be discussed. These include the barbiturates, salicylates and tranquilizers. Poisoning is also produced, not uncommonly, by carbon monoxide, organophosphorus compounds, heavy metals, chlorinated hydrocarbons, ethanol and methanol. All of these compounds are capable of producing stupor, convulsions, coma and death.

The human body is capable of detoxifying and eliminating poisons. However, when the amount of the intoxicant exceeds the capacity of the body to terminate its activity, complications and death may ensue unless therapy is initiated promptly. Therefore, therapy in acute intoxication should include: (1) prompt identification of the poison; (2) removal of the unabsorbed poison from the body as soon and as completely as possible; (3) maintenance of cardiopulmonary functions; (4) elimination of all absorbed poisons as rapidly as

---

†Neurology Service, Veterans Administration Hospital and University of Minnesota, College of Medical Sciences, Minneapolis.

possible, and (5) use of antidotes whenever feasible.

Identification of the Poison

If the patient is conscious he may be able to identify the poison as well as the amount and the time he took it. However, if he is unconscious, his clinical state and laboratory findings may prove to be the only way of identifying the intoxicant. Table 1[4,5,22] summarizes some clinical and laboratory findings in common cases of intoxication. The clinical findings observed in meprobamate and glutethimide poisoning are similar to those seen in barbiturate intoxication. Up until last year only five fatal cases of ingestion of chlorpromazine had been reported, all of them involving

TABLE 1

Important Clinical and Laboratory Findings in Common Cases of Poisoning

Drug or chemical	Clinical findings	Laboratory findings
1. barbiturates	hypoventilation patchy erythema or blisters coma	spectral analysis to identify and distinguish individual barbiturates. blood levels of about 1 mg/100 ml may be considered lethal for rapid acting barbiturates. blood levels greater than 5 mg/ml may be lethal in long-acting barbiturates.
2. salicylic acids	hyperventilation sweating hyperthermia	blood levels $>$ 30 mg/100 ml should be considered toxic. ferric chloride diacetic acid urine test positive. hypoprothrombinemia.
3. tranquilizers: phenothiazine	hypoventilation hypotension convulsion, coma extrapyramidal reaction	ferric chloride test positive in urine.
4 carbon monoxide	bright red color of the fingernails; cherry-pink lips; smell of utility gas on clothes; hypoventilation	blood: carboxyhemoglobin 60-80%; in elders, 30% or more carboxyhemoglobin may be significant.
5. organo-phosphorous compounds	pinpoint pupils cold sweating salivation muscular twitching convulsions; coma	85% or more of the red cell cholinesterase may be inhibited before there are any overt indications of poisoning.
6. lead	lead line in gingival margin; seizures disorientation auditory or visual hallucinations	stippled red blood cells coproporphyrinuria. lead excretion in urine more than 0.15 mg/l.
7. nonbarbiturate sedatives glutethimide (Doriden)	hypoventilation coma laryngopharyngeal musculature laxity	blood levels 1 mg or more may indicate poisoning.
8. methyl alcohol	hyperventilation blurry vision seizures delirium	at death, blood levels as low as 0.05% or even less may be significant.
9. cyanide	pink skin color odor of bitter almonds hypoventilation hypotension	fatal blood levels about 1 mg/100 ml.
10. morphine	pinpoint pupils greatly depressed respiration coma	morphine found in the urine and feces.

children.[3] Drug intoxication with chlordiazepoxide and diazepam have not been fatal. Although deep stupor and coma develop, little fall in blood pressure or respiratory depression has been noticed with these last two drugs.[3]

Removal of the Unabsorbed Poison

Whenever possible, an intoxicant should be removed from the stomach,[6] particularly if less than four hours have elapsed since its ingestion.[7] Many drugs that have been in the stomach for much longer periods of time can be removed in considerable amounts. For instance, since many major tranquilizers delay gastrointestinal motility and are water soluble, substantial amounts can be successfully removed hours after their ingestion.[3]

Emesis

Emesis can be induced if the patient has not vomited by the time he is seen. Emetics such as syrup of ipecac, apomorphine, dilute solutions of copper sulfate and potassium antimony tartrate are available.[7] The latter two are highly toxic and therefore not recommended. Syrup of ipecac in doses of 4-8 ml can be given by mouth. It acts as a local irritant to the stomach and also stimulates the chemoreceptor trigger zone in the floor of the fourth ventricle. Emesis is not prompt, there being a long latency period of about thirty minutes to an hour or more before its effects are felt. Apomorphine, however, is fast and dependable. Vomiting usually occurs five to 10 minutes after a single subcutaneous dose of 5 mgm in adults and 1 mgm in children. The use of emetics is not recommended if poisoning has occurred with corrosives or if the patient is comatose. Many authors do not encourage the use of emetics.[8] They do not believe these drugs are completely effective; and there is always the danger of an aspiration pneumonia. Gastric aspiration and lavage using copious amounts of water are preferred. In the unconscious patient aspiration or lavage, if done, should follow intubation or tracheotomy. The Scandinavian method of treating acute barbiturate intoxication does not recommend gastric lavage because of its low yield and the dangers of aspiration pneumonia.[9]

Absorbents

Powdered activated charcoal can be introduced into the stomach.[7] Poisons that exist in simple aqueous solutions may be absorbed readily by the charcoal. Some of them include mercuric chloride, sulfanilamide, nicotine, barbiturates, salicylic acid, alcohol, parathion and phosphorus. A saline cathartic is often given to accelerate the passage of the charcoal through the gastrointestinal tract.

Cardiopulmonary Systems

The Airway

The respiratory airway should be cleared from all secretions since over-secretion in the bronchial tree frequently occurs. Failure to do so may result in pulmonary atelectasis and pulmonary infections: the most common clinical complications of drug intoxication.[9] Tracheal intubation becomes necessary if the larynx cannot be kept clear of secretions. Intubation should not be prolonged over 36-48 hours; otherwise, it may produce a tracheolaryngitis or eventually a vocal cord granuloma.[10] Tracheotomy becomes mandatory if (1) secretions continue to be troublesome after intubation, (2) the patient has been comatose for more than 48 hours, or (3) there is no cough reflex present. Mechanical respiration is needed only when respiration begins to fail.

Ventilation

Abnormal ventilation can give rise to disturbances in the acid-base balance. The hyperventilation seen in salicylate poisoning is due to a direct effect of this drug on the brainstem respiratory center.[11] Hyperventilation decreases the partial pressure of carbon dioxide within the alveoli and arterial blood. This is followed by a rise in blood pH which, if not limited by the compensatory mechanisms of the body, will progress to a respiratory alkalosis. No specific treatment is needed to correct the respiratory alkalosis.

In barbiturate poisoning hypoventilation is secondary to hypoxemia and an accumulation of carbon dioxide.[12] Respiratory acidosis with a lowered blood pH develops as a consequence of the resulting hypercapnia. The hypoxemia, in turn, is responsible for the metabolic acidosis. Both types of acidosis will aggravate the existing hypoventilation. Therapy consists of ventilation using supernormally large ventilation volumes. Arterial CO_2 and O_2 as well as the pH should be determined in order to follow

the progress of treatment. Measurements of oxygen tension must also be made.

Pulmonary Edema

Pulmonary edema may develop as a result of a decrease in the osmotic pressure of the blood, an increase in the permeability of the pulmonary capillaries or, more likely, a distention of the capillaries of the lungs as seen in left ventricular failure.[13] Treatment would include use of oxygen, forced diuresis with osmotic diuretics if the kidneys are functioning adequately, defoaming therapy with inhalation of oxygen using a high concentration of alcohol vapor, and digitalization if needed.[13] If the patient is in a state of shock, plasma expanders such as macrodex or blood should be administered. Pressor amines are also used to maintain blood pressure.

Excretion of All Absorbed Poisons

There are many ways in which poisons can be eliminated from the body once they are absorbed. By inducing pulmonary hyperventilation, carbon monoxide and many volatile solvents such as methyl alcohol, xylene, methyl bromide, and trichloroethylene can be eliminated through the respiratory system.[9] At present there are no known ways of stimulating the biliary excretory mechanism in order to promote the elimination of poisons through the gastrointestinal tract.[7] Renal excretion of intoxicants is encouraged by the use of forced diuresis and diuretics and by altering the urinary pH.

Forced Diuresis

Forced diuresis with urea was first used in Denmark. In the U.S.A. mannitol and chlorothiazide have also been used extensively. In forced diuresis by a water load, the excess water inhibits the secretion of antidiuretic hormone by the posterior pituitary. The main effect of this excessive amount of water will be on volume and flow in the distal renal tubules and in the collecting ducts. Since foreign neutral compounds and many organic acids and bases are reabsorbed to a great extent at the proximal tubules, the water load will not increase appreciably the excretion of these substances.[7] Addition of an *osmotic diuretic* which exerts its action at the proximal tubules will decrease water reabsorption, thereby increasing the excretion of the passive solute. If urea is used, serum levels should be kept below 400-500 mg/ml. Since urea can diffuse through the proximal renal tubule, mannitol, which is a hexahydric alcohol and therefore impermeable to most cell membranes, has been preferred to urea as an osmotic diuretic.[11] In salicylate poisoning, an intravenous priming dose of 500 ml of 25% mannitol can be given in the first 30 minutes, to be followed by one liter of the solution every two hours for a total of twelve liters in 24 hours. If the urine flow has not reached 6 ml per minute after four hours, the infusion may have to be stopped. If the flow is less than 1 ml per minute, fluids should be stopped and dialysis should be considered.[14]

Diuresis can be further increased by *manipulating the urinary pH.* Many drugs and poisons are pH-dependent for excretion. Weak

TABLE 2

Hemodialyzable Drugs and Chemicals

A. *Sedatives*
1. barbiturates
2. Glutethimide (Doriden)
3. ethynylcyclohexylcarbamate (Valmid)

B. *Tranquilizers and antidepressants*
1. imipramine (Tofranil)
2. amitryptyline (Elavil)
3. meprobamate (Equanil)
4. ethclorvynol (Placidyl)
5. phenelzine (Nardil)
6. chlordiazepoxide (Librium)
7. pargyline hydrochloride (Eutonyl)

C. *Anticonvulsives*
1. diphenylhydantoin (Dilantin)
2. primidone (Mysoline)

D. *Analgesics*
1. salicylic acid
2. methyl salicylate
3. dextro propoxyphene hydrochloride (Darvon)
4. acetophenetidin (Phenacetin)

E. *Halides*
1. bromide
2. radio-iodide

F. *Alcohols*
1. methanol
2. ethanol
3. ethylene glycol

G. *Metals*
1. calcium
2. BAL—mercury complex
3. lead
4. arsenic
5. sodium
6. potassium

H. *Antibiotics*
1. streptomycin
2. kanamycin
3. penicillin
4. sulfamethoxypyridazone (Kynex)
5. sulfisoxazole
6. tetracycline
7. chloramphenicol
8. nitrofurantoin (Furadantin)
9. isoniazid

I. *Miscellaneous*
1. aniline
2. dextroamphetamine
3. thiocyanate
4. carbon tetrachloride

acids tend to be excreted more rapidly if the urine is alkaline, and weak bases will be excreted faster if the urine is acid. Only the undissociated portion of a weak acid or base will diffuse freely across the tubule cells.[14] In salicylate poisoning free salicylate excretion is dependent on the urinary pH. In an alkaline urine up to 85% of free salicylate will be eliminated, while only a low of 10% of the dose will be excreted in an acid urine.[11] Alkalinization can be accomplished by the use of sodium bicarbonate, an inhibitor of carbonic anhydrase activity like Diamox, or by an organic buffer such as THAM. In adults, infusion of 0.9% saline, 5% dextrose and 2% sodium bicarbonate given in rotation at an initial rate of about two liters per hour will produce a diuresis in excess of 5 ml per minute at a urine pH of about 7.5.[11] The use of carbonic anhydrase may lead to acidosis with resulting convulsions and papilledema.

Forced diuresis has also been used successfully in meprobamate, glutethimide and bromide poisoning.[15]

Dialysis

Hemodialysis and intermittent peritoneal dialysis are the preferred methods of dialysis and are more effective than forced diuresis.[16] Schreiner[17] states that hemodialysis is most effective if:

(a) the poison molecule can diffuse through cellophane from plasma water and has a reasonable removal rate or dialysance;

(b) the poison is well distributed in accessible body fluid compartments and not bound to protein molecules. Since the major tranquilizers are strongly bound to plasma proteins, dialysis would probably be ineffective;

(c) a relationship exists between toxicity and the blood concentration and duration of the body to exposure of this circulatory poison. Anticholinesterases do not meet this requirement. Their rapid action prevents a relationship between blood levels and clinical toxicity to be established;

(d) the amount of poison dialyzed constitutes a significant addition to the normal body mechanism for dealing with the poison.

Hemodialysis and peritoneal dialysis are the only possible ways of treating patients with grossly impaired renal function and intoxication with long-acting barbiturates eliminated through the kidney only. Hemodialysis is the method of choice in methyl alcohol intoxication and other cases of poisoning where tissue damage can occur very quickly.[15,16] Table 2 lists many drugs and chemicals that are hemodializable.[16]

If facilities for hemodialysis are not available, intermittent peritoneal dialysis using 5% albumen on the dialyzing fluid combined with alkalinization of the urine can be used. This method is less expensive, less complicated and easier to control than hemodialysis. In spite of this, pediatricians have found it more practical and certainly less complicated to use exchange transfusion in children in cases of severe poisoning.[6,11,16]

Antidotes

Antidotes can counteract the activity of a poison. Unfortunately, there are few specific antidotes available. These are listed in Table 3.[2,4,18-23]

The *chelating agents* seen in Table 3 are substances capable of forming stable covalent complexes with polyvalent metal ions. These complexes are frequently not toxic.

The *narcotic antagonists* overcome the respiratory depression caused by morphine and its derivatives. Respiration improves within minutes toward normal and consciousness may return promptly.

Specific Poisons

Organophosphorus

The organophosphorus compounds have been used in the treatment of myasthenia gravis. Their use as insecticides has been increasing steadily. They are capable of combining with acetylcholinesterase, forming a phosphorylated acetylcholinesterase compound which is unable to hydrolyze acetylcholine.[19] Accumulation of acetylcholine at the motor end plates of striated muscles and cholinergic nerve endings gives rise to weakness and paralysis of striated muscles, overactivity of the parasympathetic system, central nervous system excitation, as-

TABLE 3

Some Antidotes Used in Acute Poisoning

Antidotes	Acute poisoning by	Doses
A. Chelating agents		
1. Dimercaprol (BAL)	arsenic*	Initial injection is usually 5 mg/Kg by intramuscular injection; followed by 2.5 mg/Kg in 2 to 3 hours and a third injection of 2.5 mg/Kg 2 to 3 hours later. In the second 12-hour period, two more injections of 2.5 mg/Kg are given. Thereafter, two doses per day for 2 or more days.
2. BAL-glucoside (more soluble)	mercury* gold	
3. Calcium disodium versenate; versene	lead*	1.0 to 2.0 gm per day, best given in two infusions at 12-hour intervals in 5-day course with 2 days rest between
4. N-penicillamine	copper*	1-4 gm daily by mouth
5. D-acetyl-D, L-penicillamine (less toxic than #4, above)	lead iron mercury	
6. Desferrioxamine (D.F.M.)	iron*	5-10 gm D.F.M. in water given by stomach tube to neutralize iron in gut. Intravenous infusion of D.F.M. 90 mg/Kg body weight in 100 ml of 5% aqueous dextrose solution given over a period of 1-2 hours.
B. Narcotic antagonists		
1. Nalorphine	morphine and its derivatives	5-10 mg intravenously or 0.1 mg/Kg intravenously in children.
2. Levallorphan		1-2 mg intravenously or 0.02 mg/Kg intravenously in children.
C. Oximes		
1. 2-pyridine aldoxime methyl-chloride (2-PAM chloride, Pralidoxime chloride)	organo-phosphorous compounds	*adults:* 1 gm 2-PAM chloride intravenously at a rate not to exceed 500 mg/minute, or this amount diluted with 250 ml of sodium chloride injection and infused over a 30-minute period. A dose of 1 gm may be repeated in one hour if necessary. *children:* 20-40 mg/Kg of body weight or 0.6-1 gram/square meter of body surface of 2-PAM chloride at a 5% solution given intravenously.
D. Atropine sulfate	organo-phosphorous compounds	*adults:* 2-4 mg atropine intravenously and repeated at 5-10-minute intervals until signs of atropine toxicity appear. Some degree of atropinization should be maintained for at least 48 hours. *children:* 0.5-1 mg intramuscularly or intravenously every 10-15-minute intervals until signs of atropine toxicity appear.
	muscarine carbachol neostigmine and other quaternary ammonium compounds	0.25-2 mg atropine sulfate intramuscularly.
E. Oxygen		
1. hyperbaric oxygen 2. oxygen and 5% carbon dioxide	carbon monoxide	place patient in a pressure chamber at 2-2.5 atmospheres until levels of carboxyhemoglobin reach zero or until the patient becomes conscious.
F. Nitrites		
1. amyl nitrite 2. sodium nitrate	cyanide	inhale amyl nitrite 0.3 ml.
G. Sodium thiosulfate	cyanide	50% solution given intravenously.

*Opposite antidotes are best agents against poisoning with these metals.

phyxia and death. There is no correlation between cholinesterase depression in the blood and clinical signs and symptoms. Pralidoxime chloride should be given as soon as possible together with intravenous injections of atropine. Little is accomplished if the oxime is administered more than 36 hours after exposure to the organophosphorus poison has occurred, since phosphorylated acetylcholinesterase ages quickly, converting itself into a non-reactivable form.[19,20]

Carbon Monoxide

Oxygen is used under pressure in carbon monoxide poisoning in an effort to saturate the alveoli and blood with this gas, thus accelerating the displacement of carbon monoxide in carboxyhemoglobin. Treatment with 100% oxygen at 2 atmospheres of pressure will return consciousness within 30-90 minutes.

Cyanides

Cyanides combine with cytochrome oxidase which is an enzyme needed in cellular respiration. Methhemoglobin, produced in the blood by the administration of nitrites, competes with cytochrome oxidase for cyanide and, in so doing, aids in the regeneration of the enzyme.[4] Sodium thiosulfate is also given in cyanide poisoning. It acts by promoting the conversion of cyanide to harmless thiocyanate.[4]

Analeptic* treatment is not recommended following poisoning with depressants, as many investigators believe they are ineffective in severe poisoning.[8,12] The patient response to these drugs is transient, and there is always danger of inducing cardiac arrythmias, convulsions, visual hallucinations and psychoses.

Summary

Common drugs or chemicals producing acute poisoning include the barbiturates, salicylates and tranquilizers.

Therapy of acute intoxication includes prompt identification of the poison and its removal from the stomach by the use of emetics, gastric aspiration and lavage. The respiratory airway should be kept clear of secretions, and normal ventilation should be maintained. If necessary, blood pressure can be supported by using plasma expanders, blood or pressor amines. Renal excretion of intoxicants is encouraged by the use of forced diuresis with the aid of diuretics and by altering the urinary pH. Dialysis can also be used and is more effective than forced diuresis in removing poisons from the body. Whenever possible, antidotes should be used to counteract the activity of the intoxicant.

Finally, the use of analeptics is to be discouraged. They are thought to be inefficient in severe poisoning and capable of producing severe side effects.

OMNI-TUSS® b.i.d.

. . . **because** OMNI-TUSS is indicated for cough associated with upper respiratory tract infections, bronchitis, bronchiectasis, bronchial asthma, emphysema, sinusitis and rhinitis, hay fever, or other allergic conditions. Any of these conditions may exhibit the general symptom syndrome—coughing, wheezing, bronchospasm, and tenacious mucus—which may benefit from the antitussive, bronchodilative, antihistaminic, and expectorant action of Omni-Tuss.

The therapeutic usefulness of Omni-Tuss is enhanced by a unique resin complex formulation providing the clinically desirable advantages of: (1) uniform drug availability throughout an extended period, (2) 8 to 12 hours of symptomatic control, (3) minimal dosage requirement, (4) minimal side effects.

Economical, efficient **b.i.d.** dosage—extremely well-tolerated by children, 6-12, and adults.

'Omni Tuss' Suspension: Each teaspoonful (5 cc.) contains 10 mg. codeine (Warning: May be habit-forming), 5 mg. phenyltoloxamine, 3 mg. chlorpheniramine, 25 mg. ephedrine, all as cation exchange resin complexes of sulfonated polystyrene, and 20 mg. guaiacol carbonate.

Available on prescription only. Class X exempt narcotic. Permissible on oral prescription.

Dosage: *Adults:* 1 teaspoonful (5 cc.) q12h.
Children (6-12 *years*): ½ teaspoonful q12h.

Side Effects: Minimal, but when encountered may include jitteriness, nausea, drying of mouth, insomnia, constipation, which disappear upon adjustment of the dose or discontinuance of treatment.

Precautions and Contraindications: For complete detailed information, refer to package insert or official brochure.

new evidence for TAO® (triacetyl-oleandomycin)

a
macrolide
antibiotic for the
frequently seen
respiratory infection
in the office
and
for a problem pathogen*
in the hospital.

*Staphylococcus aureus

study I[1]

Results of a 1967 in vitro—in vivo correlation study involving 116 patients with Gram-positive coccal infections in five institutions. All patients were given TAO prior to determining the susceptibility of the offending organism.

97.0%
of the organisms were susceptible to oleandomycin*

98.0%
of the patients responded favorably to TAO® (triacetyloleandomycin)

*In some cases more than one pathogenic organism was isolated from the patient.

study II[2]

Effect of oral therapy with TAO, erythromycin, and cloxacillin on the survival time of Rhesus monkeys after intravenous inoculations of lethal doses of staphylococci, phage type 80/81. (8 monkeys in each group)

conclusion:

*Under the conditions of this study and the doses employed, it was found that

TAO® (triacetyloleandomycin)

was far superior to erythromycin, as was cloxacillin, a bactericidal agent, and of particular interest, "...bacteriostatic triacetyloleandomycin was as effective or perhaps superior to cloxacillin in preventing lethal (staphylococcal, phage type 80/81) infection."

*It should be pointed out that results obtained in an experimental study of this nature may not necessarily be directly extrapolated to the clinical situation as it pertains to man.

TAO Rx Information

INDICATIONS: Include streptococci, staphylococci, pneumococci and gonococci. Recommended for acute, severe infections where adequate sensitivity testing has demonstrated susceptibility to this antibiotic and resistance to less toxic agents. **CONTRAINDICATIONS AND PRECAUTIONS:** Not recommended for prophylaxis or in the treatment of infectious processes which may require more than ten days continuous therapy. In view of the possible hepatoxicity of this drug when therapy beyond ten days proves necessary, other less toxic agents should be used. If clinical judgement dictates continuation of therapy for longer periods, serial monitoring of liver profile is recommended, and the drug should be discontinued at the first evidence of any form of liver abnormality. When treating gonorrhea in which lesions of primary or secondary syphilis are suspected, proper diagnostic procedures, including darkfield examinations, should be followed. In other cases in which concomitant syphilis is suspected, monthly serological tests should be made for at least four months. Contraindicated in pre-existing liver disease or dysfunction, and in individuals hypersensitive to the drug. Although reactions of an allergic nature are infrequent and seldom severe, those of the anaphylactoid type have occurred on rare occasions. When used in streptococcal infections, therapy should be continued for ten days to prevent the development of rheumatic fever or glomerulonephritis. The use of antibiotics may occasionally permit overgrowth of nonsusceptible organisms. A resistant infection or superinfection requires re-evaluation of the patient's therapy. In the event such occurs with this drug the medication should be discontinued, and specific antibacterial and supportive therapy instituted.

In the complex picture of moderate to severe anxiety...

there is a new reason for prescribing Mellaril (Thioridazine HCl)

effectiveness in mixed anxiety-depression

Long recognized for its usefulness in the treatment of moderate to severe anxiety, Mellaril is now also known to be effective against mixed anxiety-depression.

Often the symptoms of anxiety states are difficult to sort out—even with the most careful probing. The patient may manifest symptoms of agitation, restlessness, insomnia, somatic complaints. But what of the depression that may be mixed in the total picture? It is reassuring to know that Mellaril may be prescribed—with strong possibilities of success—when there is anxiety alone or a mixture of anxiety and depression.

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine hydrochloride). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

Mellaril®
(Thioridazine HCl)
25 mg. t.i.d.

for moderate to severe anxiety and mixed anxiety-depression

SANDOZ SANDOZ PHARMACEUTICALS, HANOVER, N. J. 68-1

Internal Carotid Insufficiency*

WILLIAM J. RILEY, M.D., Ph.D.†
Minneapolis, Minnesota

INTERNAL CAROTID insufficiency can be defined as a symptomatic perfusional deficit in the neural field supplied by the artery of the same name. The clinical presentation of this disease depends on the circumstances peripheral to the internal carotid artery. Variations in the circle of Willis can greatly alter the neural field irrigated by the internal carotid artery, and pre-existing lesions in this neural field can greatly change the expression of a perfusional deficit.

Some individuals sustain occlusion of one, or even two internal carotid arteries without symptoms or neurologic findings. In other individuals an internal carotid artery which on subsequent pathologic examination reveals relatively little alteration from normal may be causative of severe clinical disease.

Occasionally the astute clinician will detect signs suggesting stenosis or complete occlusion of an internal carotid artery in the asymptomatic patient who is without findings of neurologic deficit. No consensus exists regarding the natural history of this condition. Many regard attempts to "relieve the obstruction and thereby enrich the circulation to the brain" in such patients as meddlesome. But some cases of internal carotid insufficiency represent instances of treatable medical emergencies.

Etiology

Of the many potential causes of internal carotid insufficiency including the several types of vasculitis, osteoarthritis, local tumor, trauma, and arterial fibromuscular dysplasia, only atherosclerosis will be discussed. In our culture this is the most prevalent cause of internal carotid insufficiency. Accompanying this process are changes such as lumenal narrowing, intimal ulceration, and elongation causing tortuosity and kinking. Each of these changes may produce reduction of blood flow in some

*Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.

†Assistant Professor of Neurology, University of Minnesota and Assistant Chief of Neurology, Hennepin County General Hospital.

individuals and thereby contribute to the cerebral symptomatology of this disease.

Pathogenesis

With elongation and tortuosity of the internal carotid artery the redundancy of the vessel may allow it to become kinked at a site of connective tissue fixation or become otherwise so mechanically trapped as to reduce its lumen and the flow of blood to the neural field it irrigates. Clinical symptoms in this situation are often precipitated by movement of the neck or by constricting clothing.

With progressive reduction of the lumen of the vessel by an atherosclerotic plaque, usually just above the common carotid bifurcation, the field of irrigation becomes increasingly dependent on collateral or substitutive vessels. When finally the collateral channels cannot supply the metabolic needs of the neural field there is the onset of intermittent, progressive, or permanent symptoms of internal carotid insufficiency.

If there is disruption of the integrity of the intima of the internal carotid artery, as from an ulcerated atherosclerotic plaque, the possibilities of embolism threaten the perfused field. Emboli may be small like the microemboli of cholesterol crystals, fibrin, or platelet aggregates, or large as with fragmentation of or seeding from a thrombus on the plaque. The symptoms of disease may be intermittent, progressive, or permanent.

Symptoms and Findings

A characteristic and initial sign of internal carotid insufficiency is sudden transient monocular blindness with sensory and/or motor deficit on the side contralateral to the involved vessel. The latter is usually more pronounced in the face and hand than in the leg. If the major hemisphere is involved, aphasia may be an additional feature.

This clinical presentation derives from the usual cerebrovascular pattern in which the ophthalmic artery is the first major intracranial branch from the internal carotid artery; and the middle cerebral artery field of irrigation is largely dependent on the internal carotid artery, with a relatively disadvantaged relationship to potential collateral supply.

*See Test Your Word Score Page 1213.

Transitory Neurologic Dysfunction

From this classic picture there are many variations. Some of the previously mentioned features may appear without the complete ensemble. An unusual mode of presentation is progressive dementia with quadriparesis; but such an unusual presentation requires consideration of possible complicating features or other predisposing causes. Symptoms may include headache, mental changes, transient loss of consciousness, visual disturbances, seizures, disorientation, drowsiness, and emotional lability. It is said that more than 40% of patients with carotid artery insufficiency have warning symptoms of transitory neurologic dysfunction prior to the onset of a permanent deficit.

Localizing Findings

On examination the patient may have a wealth of localizing findings during a clinical attack or may have no abnormalities on detailed investigation between attacks. Aside from the localizing value of a motor or sensory deficit, suggestive findings include a significant bruit over the carotid bifurcation, reduction of pulsations either over the carotid artery palpated in the neck, or over the internal carotid artery palpated in the oral pharynx. Other findings may include: (1) an ipsilateral* Horner's syndrome due to damage to the cervical sympathetics in the carotid sheath, (2) an ocular bruit over the ipsilateral eye, or (3) an ipsilateral optic atrophy due to pressure on the optic nerve from an enlarged ophthalmic artery (flowing retrograde as a collateral for the insufficient internal carotid artery).

Bedside Studies

Useful bedside investigations include ophthalmo-dynamometry, the determination of pressure in the central retinal artery, the arm-to-retina fluorescein circulation time, and thermography or the more simple measurement of temperature over the medial half of the forehead bilaterally. This area is perfused by the ophthalmic artery and can therefore be an indicator of internal carotid flow. Carotid compression tests at the bedside are potentially hazardous and should not be done without electroencephalographic and electrocardiographic monitoring.

Diagnostic Aids

In the patient who has sustained cerebral infarction in consequence of internal carotid insufficiency the electroencephalogram or brain scan may be of diagnostic aid. A series of either of these and especially a series of both may help to separate a case of internal carotid insufficiency with cerebral infarction from a cerebral tumor. Usually the routine laboratory work, chest and skull x-rays, echoencephalogram, and lumbar puncture are of little value. A special modification of the encephalogram test is occasionally of great value in diagnosing or screening. To conduct this test the patient is given 0.6-1 mg. of atropine I.M. one-half hour prior to the test to block vasovagal cardiac slowing. He is then connected for encephalogram recording with one channel recording an electrocardiogram trace. Each of the carotid arteries in the neck is then massaged to test for adequacy of atropinization as well as for extreme cerebral dependence on flow through that carotid. If no changes such as clinical symptoms, electrocardiogram slowing or encephalogram abnormalities are produced, each carotid artery is compressed in turn for 30 seconds or until changes are noted. The emergence of clinical symptoms or localized encephalogram abnormality in the absence of slowing of the heart rate is regarded as presumptive evidence that the responsible area of cerebrum has a critical dependence on the compressed carotid artery. The finding of symptoms emanating from the hemisphere contralateral to the compressed carotid artery or the appearance of an encephalogram abnormality in the contralateral hemisphere, along with absence of similar findings from compression of the ipsilateral carotid artery, suggest insufficiency or complete occlusion of the carotid artery ipsilateral to the changes.

A definitive diagnosis rests on clinical suspicion plus adequate arteriographic study. Usually an adequate study requires visualization of at least three and usually all four cervicocranial vessels either by aortography or by direct puncture angiography.

Therapy and Prognosis

Already alluded to have been the different time courses with which symptoms of this entity may present: transient and recurring, progressive, or permanent. Consideration of the time course is a major deciding factor for both treatment and prognosis. For the patient with findings that may be due to internal carotid insufficiency the time course cannot be predicted. Will the findings remain stable? Will they progress? Will they relent? It is this very uncertainty that makes the patient a potential medical emergency.

Those patients with stable neurologic deficit with or without a history of antecedent transient attacks or a subacute onset prior to being seen represent cases of completed stroke syndrome. Their care need not differ from that given other patients with completed stroke.

Anticoagulation

For those patients with a relatively mild deficit and progressive disability over a period of observation urgent attention is required; if possible the progress of the stroke must be halted and hopefully reversed. After intracerebral and subarachnoid hemorrhage have been excluded by a clear lumbar puncture, and when the diagnosis is reasonably certain, immediate anticoagulation with heparin followed later by a coumadin derivative is required in the absence of severe hypertension, bleeding tendency, or other contraindication to anticoagulants. Other measures, such as intravenous papaverine, low molecular weight dextran, and intermittent inhalation of 5 per cent CO_2, are still under study. After anticoagulants are begun and the patient has stabilized, consideration can be given to elective arteriography to demonstrate the causative lesion. When any doubt exists as to the diagnosis, anticoagulation may be deferred until after a definitive diagnosis is established by arteriography.

Arteriography

It is particularly important to exclude such diagnoses as cerebral tumor, and subdural or epidural hematoma which may occasionally appear as a progressing stroke. For this reason arteriography often precedes anticoagulation.

In the unequivocal case of the patient with internal carotid insufficiency already anticoagulated and now being investigated by elective arteriography, it will be necessary to study the majority of the cervico-cranial vessels before

deciding on surgical correction of the lesion. Because such an investigation is extensive and has a distinct morbidity and mortality rate, it should not be undertaken unless adequate vascular surgery facilities are available. Since this investigation is time-consuming and has the potential of further impairing the already marginal blood supply, many prefer to have the patient already receiving the benefits of prophylactic anticoagulation before the investigation is undertaken.

Transient Ischemia

Some patients present with no findings of neurologic deficit but a history of transient ischemic attacks. They may have other findings compatible with a diagnosis of internal carotid insufficiency such as a cervical bruit. Other patients may be seen for the first time during an attack of insufficiency but are observed to clear completely in a brief time. In these patients an elective evaluation can be undertaken with emphasis on safety and completeness. If, in such patients as these, the diagnosis of internal carotid insufficiency be sustained, a decision regarding therapy can be made. Before this decision is made, however, the hazards to the patient from the induced hemorrhagic diasthesis should be weighed against the frequency and severity of the transient ischemic attacks he has had. In treating with anticoagulants the patients suffering from transient attacks of cerebral ischemia, the only benefit established is a reduction in the number and severity of the attacks. There is as yet no demonstrated protection from an eventual stroke. This limited benefit must be weighed against the hazards of anticoagulation and special attention given to any existing "relative" contra-indications.

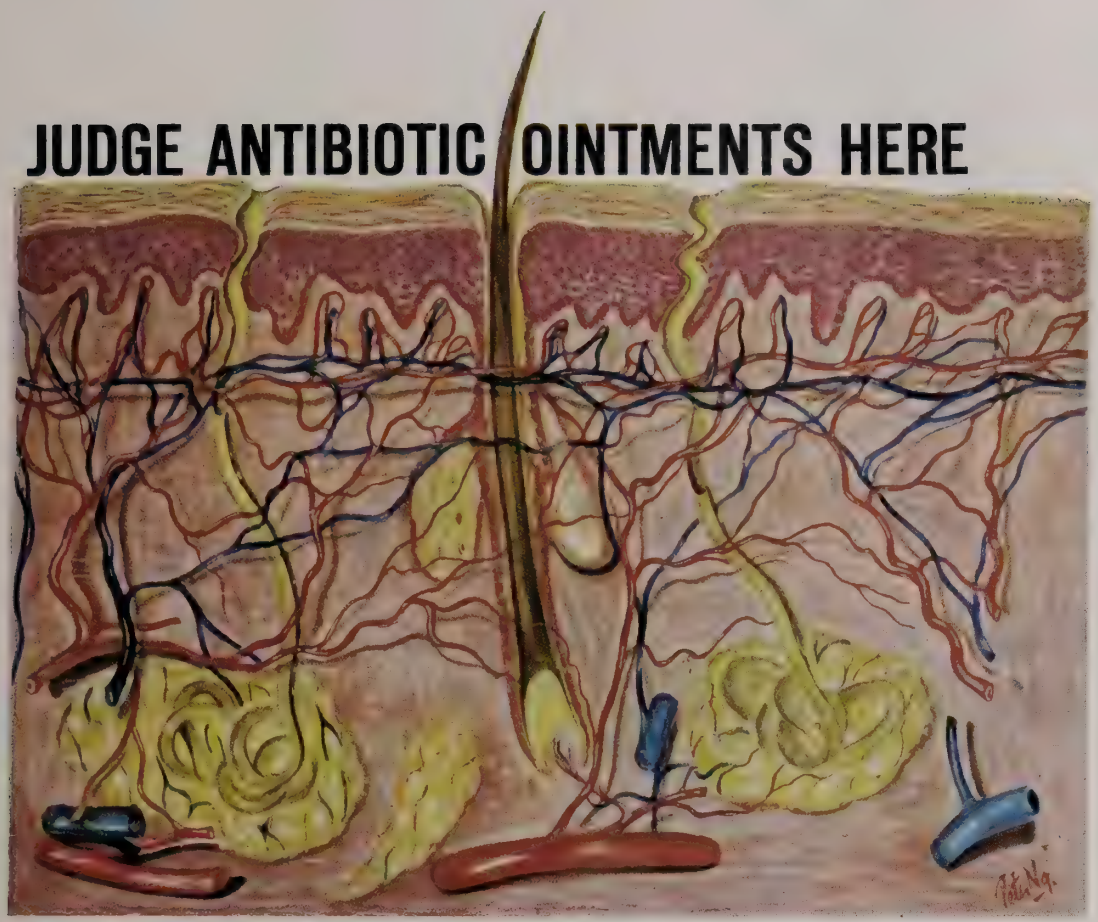
Surgical

When localized, surgically accessible, extracranial occlusive vascular disease is found, it should be corrected by a competent vascular surgeon. In cases where the vascular occlusive process is too scattered, where there is extensive intracranial vascular disease which appears more significant than that in the neck, or where the patient refuses surgery, consideration can be given to long-term treatment with anticoagulants.

Conclusions

By internal carotid insufficiency we mean that circumstance in which the symptoms and signs of neurologic deficit suggest that their cause is an inadequate perfusion through either or both of the internal carotid arteries.

Patients whose disease is due to this pathogenetic mechanism and who show progressive neurologic deficit represent medical emergencies. The keystone to successful management of patients with a progressing stroke due to internal carotid insufficiency is recognition of the evolving pattern of neurologic deficit and appreciation of the need for immediate diagnostic and therapeutic measures. This recognition depends on careful observation of the patient for evolution of symptoms or signs suggesting progressive deficit. Such a patient needs immediate institution of measures to support and increase the flagging local cerebral circulation. These measures include, but may not be restricted to, immediate anticoagulation and the surgical correction of the appropriate vascular obstruction. Diagnostic studies must advance rapidly so as not to delay appropriate therapy.



The patient with transient attacks of cerebral ischemia due to internal carotid insufficiency also requires careful appraisal and management; but the workup of his problem is an elective one. The patient with stable neurologic deficit due to internal carotid insufficiency presents no emergent problem and requires only the usual careful attention to supportive general medical management and rehabilitative care.

The ears are the last feature to age.—Chazal

JUDGE ANTIBIOTIC OINTMENTS HERE

Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Complete literature available on request from Professional Services Dept. PML.

'NEOSPORIN'®

POLYMYXIN B-BACITRACIN-NEOMYCIN OINTMENT

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

Muscle in Spasm

and Valium (diazepam)

The ability of Valium to help relieve skeletal muscle spasm—as well as psychic tension—demonstrates its clinical value and versatility.

The muscle-relaxant effect obtained with Valium, used adjunctively with other drugs or physiotherapy, favorably affects the entire cluster of spasm-related symptoms . . . helps accelerate return to normal activity.

When skeletal muscle spasm and psychic tension coexist, the calming effect of Valium is an added therapeutic benefit that contributes to the total management of the patient.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms have occurred following abrupt discontinuance. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation, have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Valium®(diazepam)
2-mg, 5-mg, 10-mg tablets

It might have been different with **Butazolidin® alk**

100 mg. phenylbutazone
100 mg. dried aluminum hydroxide gel
150 mg. magnesium trisilicate
1.25 mg. homatropine methylbromide

If it doesn't work in a week, forget t

But please don't forget this:

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently. Large doses of the alka formulation are contraindicated in glaucoma.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Persistent or severe dyspepsia may indicate peptic ulcer; perform upper gastrointestinal x-ray diagnostic tests if drug is continued. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with caution in the first trimester of pregnancy and in patients with thyroid disease.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make complete blood counts at weekly intervals during early therapy and at 2-week intervals thereafter. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The more common are nausea and edema. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately before or after meals or with milk to minimize gastric upset. Drug rash occasionally occurs. If it does, promptly discontinue the drug. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), or a generalized allergic reaction similar to serum sickness may occur and require permanent withdrawal of medication. Agranulocytosis can occur suddenly in spite of regular, repeated normal white counts. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, hypersensitivity angiitis, pericarditis and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Painful Shoulder: Initial: 3 to 6 capsules daily in 3 or 4 equal doses. Trial period: 1 week. Maintenance dosage should not exceed 4 capsules daily; response is often achieved with 1 or 2 capsules daily.

In selecting the appropriate dosage in any specific case, consideration should be given to the patient's weight, general health, age and any other factors influencing drug response. (6)R 46-070-A

Myasthenia Gravis*

Emergency Treatment

WILLIAM R. KENNEDY, M.D.†
Minneapolis, Minnesota

MYASTHENIA GRAVIS is one of the few muscle diseases for which adequate therapy is available. The existence of treatment poses an obligation upon the physician to consider this diagnosis in any patient with intermittent muscle weakness.

The initial symptoms appear in the muscles innervated by the cranial nerves. The most frequently encountered symptom is extra-ocular muscle weakness resulting in intermittent diplopia and ptosis. Dysarthria, dysphagia, fatigue of jaw muscles during meals and difficulty holding the head upright are common complaints. Sometimes the weakness is confined to these muscles, but more often the limb muscles become affected. As in most other muscle disorders the proximal girdle muscles are weaker than those located more distally in the extremities. Spontaneous remissions are common.

The diagnosis of myasthenia gravis can usually be made by history and examination, supplemented by the use of pharmacological test substances. Nerve stimulation studies are always useful and sometimes indispensable for confirming the diagnosis. Because the present discussion is restricted to emergency situations, it will be assumed that the diagnosis has been adequately established.

Mechanism

Weakness, the main manifestation of myasthenia gravis, is due to an abnormality of manufacture, transfer or storage of acetylcholine in the nerve terminal portion of the motor endplate. Each nerve impulse triggers the release of acetylcholine from the nerve terminal into the neuromuscular function; this in turn inaugurates depolarization of the muscle membrane. When depolarization reaches a threshold level, a propagated muscle action

*This work was supported in part by funds received from Easter Seal Research Foundation of the National Society for Crippled Children and Adults.

Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.

†Assistant Professor, Division of Neurology, University of Minnesota.

potential is initiated and the muscle fiber contracts. But, because the myasthenic nerve terminal releases suboptimal amounts of acetylcholine, arrival of a nerve impulse does not always result in contraction of the muscle fiber. The probability of failure is increased by repetitive nerve stimulation or exercise, both of which cause an increase in the neuromuscular defect which lasts for 15 to 20 minutes. The myasthenic patient requires this time period before strength returns to preexercise levels.

Emergencies

The myasthenic patient becomes involved in emergency situations because of (1) myasthenic crises (too little medication) or (2) cholinergic crises (too much medication).

Myasthenic Crisis

Myasthenic crisis becomes evident as an increase in myasthenic symptoms during a superimposed illness, usually of an infectious nature. The patient notices that the customary dosage of anticholinesterase does not have its usual strengthening action. Then he uses more medication to obtain the desired effect but soon finds the increased dose insufficient.

The onset of ptosis results in a sleepy appearance, sometimes accompanied by compensatory wrinkling of the forehead. Weakness of the jaw muscles causes sagging of the jaw which is supported by the hand. Weakness of the neck muscles may make it difficult to hold up the head. The extremities are also involved, first the proximal hip and shoulder girdle muscles, later the more distal muscles.

Dysarthria, dysphasia, shortness of breath, inability to cough forcefully and weakness of the respiratory muscles lead to bronchitis, pneumonitis and atelectasis. Collapse of the pharyngeal muscles and tongue can cause obstruction of the airway. Death is frequently due to respiratory failure.

Cholinergic Crisis

Cholinergic crisis can be suspected when the patient reports an increase in weakness about one hour after taking anticholinesterase medication. The distribution of weakness produced by overdose is similar to that associated with myasthenia. Certain side reactions also help indicate that excess drug has been taken. These include an increase in salivation and sweating, gastric distress or nausea, abdominal cramps, bradycardia and fasciculation of muscle. Since these reactions are not a consistent feature of cholinergic crisis their absence does not assist in diagnosis. Thus in many cases the cause of crisis remains uncertain.

Treatment

The drugs found to be most useful for treatment are the following anticholinesterases: neostigmine bromide (Prostigmine bromide), pyridostigmine bromide (Mestinon bromide), ambenonium chloride (Mytalase chloride) and edrophonium chloride (Tensilon). These do not enhance release of increased amounts of acetylcholine; they attack the problem indirectly, by slowing destruction of existing acetylcholine, thus allowing it prolonged contact at the muscle membrane. A disadvantage of this type of medication is that acetylcholine in excessive amounts inhibits neuromuscular conduction. The physician must therefore teach the patient to take enough medicine to prevent weakness, yet to avoid an excessive dose, which also induces weakness.

Emergency treatment

The logical treatment at the onset of the sequence of events of myasthenic crisis is to increase anticholinergic medication. However, the drugs often have a diminishing effect because the patient has become refractory to their action. At times it is difficult to determine if more medication is needed or whether the patient has ingested excessive medication and is in cholinergic crisis. The edrophonium chloride (Tensilon) test is often useful in making the distinction. An increase in strength following the intravenous administration of 1-2 mg indicates a need for more anticholinesterase medication. The primary evaluation should center upon the muscles of respiration and those innervated by the cranial nerves. If the improvement is not definite the patient should be presumed to be in cholinergic crisis and all medication discontinued for 72 hours.

Adequate Respiration

Regardless of etiology, the first concern of

the physician should be the establishment of adequate respiration. The patient with advancing weakness must be hospitalized immediately. If there is any indication of respiratory embarrassment tracheotomy should be performed, and if necessary, respiration should be given mechanical assistance. The positive pressure type respirators such as the Bird valve are the most useful. Secretions should be removed frequently by suction. Antibiotics are used prophylactically. Constant competent nursing care is obligatory. Nutrition can be maintained by intravenous feedings or via a gastric tube. If the patient cannot speak or write, a simple communication system using eyeblinks or other movements should be established. After 72 hours, retreatment with anticholinesterase medication is cautiously resumed. The edrophonium chloride (Tensilon) test is useful as a guide to dosage.

Conclusions

The discharged patient must establish close communication with the physician. All illnesses, particularly those of an infectious nature, and any unusual change in requirement for medication must be reported so that future emergencies can be prevented.

Healing Takes To The Highway

The first doctor trudging out of a primitive settlement to an isolated hut in a forest clearing, and the modern specialist zooming along a cement road in a high-powered car, are both on the same errand. From the very beginning doctors have gone on just such errands. They probably always will. By virtue of their calling the sons of Esculapius are, in a measure, itinerant.

We find physicians among the early settlers on the boats going to Massachusetts and to Jamestown and even the Swedes in Delaware had their barber-surgeon. The Dutch provided not only for preachers and teachers but for "comforters of the sick"—Zieckentrooster—who were often schoolmasters. Penn brought two doctors with him, but Pennsylvania appears to have been a poor place for them in the beginning, for in his diary Gabriel Thomas writes, "Of lawyers and doctors I shall say nothing, because the country is peaceable and healthy." We find them in almost every settlement, however, and when not present, the community depended on barbers, midwives, and the doctors who chanced to be on boats for medical attention.

Many men of affairs took up doctoring as a gentleman's side-line. Governor John Winthrop of Connecticut practiced medicine as an avocation, rode about treating patients in Massachusetts and Rhode Island as well as in his own province, and he even dared prescribe for them by letter. He used a famous cure-all called "rubila." Some of the physicians were storekeepers, some teachers, some parsons. Dr. Abram Staats of New Amsterdam was also a fur trader. Dr. Jasper Gunn of Connecticut practiced surveying and mended kettles to make ends meet between sick calls. Bishop Seabury, the first Anglican Bishop of America, studied medicine as part of the missionary's equipment for Holy Orders. Griffith Owen, a physician who came to America with Penn, visited the neighbouring provinces preaching and healing as well.*

Treatment of Tetanus*

A. B. BAKER, M.D.†
Minneapolis, Minnesota

MOST OF THE current concepts of the pathogenesis of tetanus agree that its development is dependent upon multiplication of the organisms and production of a soluble toxin. It is this toxin which produces the symptoms. According to Abel's experiments, serum therapy is powerless to mitigate or abolish the lethal effect of the tetanus toxin once a certain dose has been fixed by the nervous system. The ideal treatment, therefore, would be to combat the fixed toxin. Such a therapeutic agent is not available. Accordingly, the treatment has centered about controlling the manifestations and preventing their progression to a fatal issue.

Cause of Death

A knowledge of the usual causes of death in this disease is most essential to any consideration of treatment. In tetanus death usually results from one of five causes: namely, spasm of the glottis, with diaphragm and intercostal muscles resulting in asphyxia; toxic encephalitis; exhaustion; medullary failure; secondary pulmonary infection. In a number of cases it is very difficult to distinguish between death from exhaustion and medullary failure; in both there often occur changes in pulse, respiration and temperature. It is our feeling that most fatalities considered due to exhaustion are actually due to unrecognized medullary failure. Pathological studies in a number of our cases tend to lend proof to such a concept.

Treatment

Treatment in tetanus has centered around measures to prevent the above complications.

Excision of the Wound

Since the tetanus bacillus produces its toxin from a focal area, it would seem logical to radically remove the focus of infection and thereby prevent further manufacture of the toxin. Opinions in the literature as to the

* Presented at the Continuation Course in Neurological Emergencies sponsored by the University of Minnesota, Minneapolis, November 8, 1967.

†Professor and Director, Division of Neurology, University of Minnesota.

efficacy of this procedure have been controversial. If the present concept of the pathogenesis of this disease is correct, then it would seem to be most essential to radically remove the focus of infection whenever such a focus can be found.

Neutralization of the Circulating Toxin

Opinion has differed with respect to use of serum once symptoms have developed. Experimentally it has been shown that once a lethal dose has been fixed by nervous tissue, antitetanic serum is powerless to mitigate the course of the disease. Since, for practical purposes, it is impossible to determine if this has occurred clinically, it has been thought advisable to give adequate antitoxin to all patients suffering from this disease. A reasonable schedule consists of the administration of 60,000 units during the first 24 hours and 20,000 to 40,000 units daily for the next few days. With the newer tendency to radically remove the focus of infection it would not seem necessary to maintain a high serum level of antitoxin for any length of time. Where the wound is extensive and cannot be completely removed, or where the focus cannot be found, a larger dose and a longer period of administration would logically be indicated.

Intraspinal serum has been gradually discarded because of the dangers in its use and the lack of proof that it has any advantage over the parenteral route.

Sedation

Environmental and pharmacologic sedation has been repeatedly cited as the cornerstone of treatment. Absolute quiet, a dark room and sedation have been considered of great importance in preventing and controlling the muscle hyper-irritability occurring in this disease. The most popular drugs for this purpose have been avertin, the barbiturates, chloral hydrate, paraldehyde and thorazine. The great disadvantage of these drugs is that in the more severe cases, doses which control the symptoms also greatly suppress respiration and predispose to respiratory infections.

Paraldehyde, in our experience, has been one of the best drugs when administered rectally, orally, or intramuscularly with alteration of the routes because of its irritative properties. The dosage must be regulated according to the response of the patient and can frequently be reduced if curare and other such drugs are used concomitantly.

Curare and Curare-like Drugs

It is not surprising that Claude Bernard, who showed that curare had its primary action at the myoneural junction, should have suggested that this substance be used in the treatment of tetanus. The first case was treated in Hoche in 1894. Curare possesses certain theoretical advantages over the sedatives previously used since it permits relaxation without the prolonged respiratory depression and interference with vegetative functions which were present with the usual sedatives. However, the use of curare is somewhat impracticable, since it has to be given intravenously and its action is very short. This necessitates frequent injections and continuous attention by the physician in order to combat toxicity and the side effects of hypersecretion and bronchospasm. A suspension of curare in wax and oil has been used in the treatment of various spastic conditions. We have used intramuscular curare in the treatment of three cases of tetanus. While in all the cases there seemed to be some subjective relief, in only one case was it felt that the amount of sedation required was considerably reduced by the concomitant use of curare.

Penicillin

Knowledge that penicillin inhibited the growth of clostridium tetani naturally stimulated interest in the effect of the antibotic on the disease. It is generally agreed that the organism remains at the site of the wound, multiplies, and produces its toxin locally. However, recovery of the organism from various organs in four fatal cases by Mayer indicates that a bacteremia may occur. Several reports of small series of patients treated with penicillin have been published with statements that in the cases discussed the drug "would seem" to be or "is apparently" life-saving or beneficial. As all were uncontrolled cases, one cannot draw any conclusions from them. Generally, it appears that penicillin has very little effect upon the disease itself. Use of this drug is of utmost importance, however, in combating the secondary pulmonary complications that often prove fatal. It is for this purpose that

we have instituted the routine use of penicillin in all cases of tetanus admitted within the past few years.

Tracheotomy and Oxygen Therapy

In 1942 Baker demonstrated marked nerve cell changes in certain cell groups in the medulla in tetanus. While the clinical signs and the mode of death in this disease had often seemed consistent with medullary failure, this cause had previously been given little consideration. Moreover, even under the best regulation of sedation it is often impossible to totally avoid acute laryngospasm which acts as a constant threat of death from asphyxia and can seldom be averted by intubation because of the coincident trismus. We are convinced that the institution of early tracheotomy and supplemental oxygen therapy have been of great value in preventing this occurrence. Accordingly we have instituted early tracheotomy in order to avoid hypoxia to the medulla and to insure an adequate airway in the event of spasm of the laryngeal muscles. Also the presence of a tracheotomy facilitates the administration of continuous oxygen, thus giving an added safety factor. We wish to emphasize the early and elective nature of this procedure.

The Doctor

There are men and classes of men that stand above the common herd: the soldier, the sailor, and the shepherd not infrequently; the artist rarely; rarelier still, the clergyman; the physician almost as a rule. He is the flower (such as it is) of our civilization; and when the stage of man is done with, and only to be marvelled at in history, he will be thought to have shared as little as any in the defects of the period, and most notably exhibited the virtues of the race. Generosity he has, such as is possible to those who practice an art, never to those who drive a trade; discretion, tested by a hundred secrets; tact, tried in a thousand embarassments; and what are more important, Heraclean cheerfulness and courage.*

*Robert Louis Stevenson

Soul

O who shall, from this Dungeon, raise,
A soul inslav'd so many ways?
With bolts of Bones, that fetter'd stands
In Feet; and manacled in Hands.
Here blinded with an Eye; and there
Deaf with the drumming of an Ear.
A Soul hung up, as 'twere, in Chains
Of Nerves, and Arteries, and Veins.
Tortured, besides each other part,
In a vain Head, and double Heart.

—Marvell

One's eyes are what one is; one's mouth, what one becomes—Galsworthy

She isn't burdened by her hypertension or her therapy...

Butiserpazide® lowers blood pressure so smoothly that patients are often untroubled by either the disease...or treatment

BUTISERPAZIDE provides not only the classic thiazide/reserpine formula; it supplements it with the mildly sedative effect of BUTISOL (butabarbital).

Clinical comparisons have shown that many patients respond to this treatment with (1) smooth, uniform lowering of blood pressure[1]...at times *below* the levels attained with previous therapy[2]; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness[2]; plus (3) "...lowered incidence of drug side effects."[2]

And BUTISERPAZIDE offers an added advantage: the usual dosage is just 1 tablet once or twice daily. It is available in two strengths for dosage flexibility.

Are there any hypertensives in *your* practice who might find life a little pleasanter on BUTISERPAZIDE?

Contraindications: Sensitivity to any component, porphyria, peptic ulcer, ulcerative colitis, mental depression, renal impairment or shutdown. **Warnings:** Consider the possibility of sensitivity reactions in patients with history of allergy or bronchial asthma. Coated potassium tablets, sometimes administered in conjunction with antihypertensive therapy, may be associated with small bowel lesions, which have led to obstruction, hemorrhage and perforation. Surgery has frequently been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occur. *Use in Pregnancy:* Exercise caution, since thiazides cross the placental barrier and may cause fetal or neonatal hyperbilirubinemia, thrombocytopenia or altered carbohydrate metabolism; adverse reactions seen in the adult may occur in the newborn. Use reserpine in women of child-bearing age only when essential to patient welfare. Increased respiratory secretions, nasal congestion, cyanosis, and anorexia may occur in infants born to reserpine-treated mothers. **Precautions:** *Butisol* (butabarbital)—Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression. *Hydrochlorothiazide*—May induce electrolyte imbalance; when used with digitalis or one of its glycosides and in patients with severe hepatic insufficiency, cardiac arrhythmias or symptoms of impending hepatic coma may occur. Discontinue and institute appropriate countermeasures if prolonged use produces hypokalemia or (likely with sodium restriction) hyponatremia and hypochloremic alkalosis. (Ammonium chloride, used to reverse hypochloremic alkalosis, is contraindicated in hepatic disease.) May produce elevated serum uric acid levels (and, infrequently, gout) or reduce glucose tolerance, altering insulin requirements in diabetics. *Reserpine*—Observe for signs or symptoms of peptic ulcer or ulcerative colitis. Discontinue at first sign of mental depression; keep in mind possibility of suicide. Exercise extreme caution in history of mental depression. May produce cardiac arrhythmias when used with digitalis and quinidine, or may precipitate biliary colic in patients with gallstones. Discontinue 1 to 2 weeks before surgery; inform the anesthetist in event of emergency surgery. Exercise caution in history of epilepsy. Discontinue 1 to 2 weeks before ECT. *General*—Exercise caution in coronary artery disease. **Adverse Reactions:** Dizziness, drowsiness, weakness, nasal congestion, leg cramps, nausea, palpitations, superficial skin bruises, palmar erythema, headache, dehydration, skin rash, "hangover," systemic disturbances, diarrhea, itching, vomiting, paresthesia, photosensitivity, pancreatitis, jaundice, xanthopsia, purpura, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, anorexia, gastric irritation, abdominal cramping, constipation, glycosuria, vertigo, cutaneous vasculitis, orthostatic hypotension (potentiated by alcohol, barbiturates, or narcotics), increased salivation and gastric secretion, increased intestinal motility, loose stools, angina-like syndrome, arrhythmias, bradycardia, flushing, hypotension, nervousness, paradoxical anxiety, rarely atypical Parkinsonian syndrome, central nervous system sensitization (manifested by dull sensorium, deafness, glaucoma, uveitis, optic atrophy), dryness of mouth, syncope, epistaxis, weight gain, and impotence or decreased libido. **Usual Adult Dosage:** BUTISERPAZIDE®-25 or BUTISERPAZIDE®-50: 1 tablet daily or b.i.d. When used with other antihypertensive agents reduce dosage of both drugs about 50% and observe carefully for changes in blood pressure. ***Before prescribing or administering, see package insert.*** **References: 1.** Johnson, H. J., Jr.: Penna. M. J. **67**:35, 1964. **2.** Coodley, E. L.: Curr. Ther. Res. **4**:460, 1962.

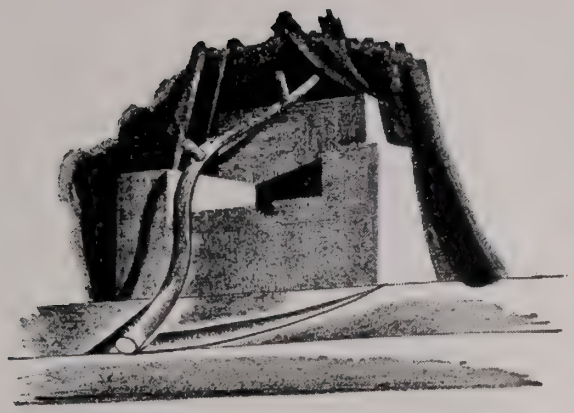
McNEIL

McNEIL LABORATORIES, INC.
FORT WASHINGTON, PA.

New drugs take exams, too.



Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

In Memoriam

Thou know'st 'tis common; all that lives must die,
Passing through nature to eternity.—Shakespeare

FREDERICK A. LOVE, M.D.

Dr. Frederick A. Love, 80, who for more than 50 years practiced medicine in Carlos, died June 5. Born in Preston, Dr. Love attended Hamline University and completed his medical training at the University of Minnesota.

He was a member of the American Medical Association and the Park Region District and County Medical Society and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his wife, a daughter and two sons.

RUDOLPH E. HULTKRANS, M.D.

Dr. Rudolph E. Hultkrans, 68, Minneapolis surgeon, died June 12. Dr. Hultkrans attended the University of Minnesota and received his medical degree in 1926.

He was a member of the American Medical Association, the Hennepin County Medical Society and an Associate Member of the Minnesota State Medical Association.

He is survived by his wife and a son.

WALDEMAR G. JOHANSON, M.D.

Dr. Waldemar G. Johanson, 62, St. Paul physician, died June 18 in Bethesda Hospital after a heart attack. Dr. Johanson practiced medicine as a family doctor for 36 years on Payne Avenue and the East Side.

He was a graduate of the University of Minnesota Medical School and a member of the Ramsey County Medical Society, the American Medical Association and the Minnesota State Medical Association. Dr. Johanson was also a member of the Ramsey County Historical Society, the Minnesota Historical Society, the American Swedish Institute and the American Swedish Pioneer Historical Society.

He is survived by his wife, two daughters and one son.

ROY M. MAYNE, M.D.

Dr. Roy M. Mayne, tuberculosis specialist, died May 25. Born in Shelby, Iowa, Dr. Mayne attended the State University of Iowa, College of Medicine, and received his degree in 1921. In 1927 he joined the staff at the Nopeming Sanatorium, Nopeming, Minnesota.

He was a member of the American Medical Association and St. Louis County Medical Society and an Associate Member of the Minnesota State Medical Association.

He is survived by his wife, a daughter and two sons, one of whom is Dr. John G. Mayne of Rochester.

RICHARD BARDON, M.D.

Dr. Richard Bardon, 71, Duluth physician, died June 3, after a brief illness. He was born in Superior, Wisconsin, and attended Northwestern University Medical School, Chicago, graduating in 1924.

For some years, Dr. Bardon was chairman of the Duluth Diabetes Detection Drive and had served as chief of staff of St. Mary's and Miller Memorial hospitals. He was a member of the American Medical Association, the American College of Physicians, the American Diabetes Association, the Minnesota Society of Internal Medicine, the St. Louis County Medical Society, and the Minnesota State Medical Association. A recognized authority on local and Northern Minnesota history, Dr. Bardon was president of the St. Louis County Historical Society for 17 years and a member of the board of the Minnesota State Historical Society. He co-authored a historical book on early Minnesota fur traders, entitled "Fur Traders Reminiscences."

He is survived by his wife and three sons.

MARGUERITE SCHWYZER, M.D.

Dr. Marguerite Schwyzer, 58, St. Paul physician, died unexpectedly of pneumonia, in Zurich, Switzerland. She had been traveling abroad for about a month.

Born in St. Paul, she had practiced medicine in St. Paul for a number of years. In recent years her practice was with the University of Minnesota Student Health Service and the Wilder Foundation.

In 1960 she worked with Dr. Tom Dooley's "Medico" team in Haiti in the Caribbean and at one time had lived in Europe, Africa and Asia.

She is a member of the American Medical Association, the Minnesota State Medical Association and the Ramsey County Medical Society.

Dr. Schwyzer is survived by two brothers, Dr. Arnold Schwyzer, Bronxville, New York, and Dr. Hanns Schwyzer, Raton, New Mexico.

NORTHLANDS REGIONAL MEDICAL PROGRAM

REGIONAL PROGRAM FOR HEART DISEASE, CANCER AND STROKE

The Operational Program Application

On July 30, we sent twenty copies of a large document, the first Operational Grant Request, to the Division of Regional Medical Programs in Bethesda, Maryland. Our goal is to fulfill the requirements to move from the "talking phase" (planning) to the "doing phase" (operational), starting January 1, 1969. The 1000 page operational grant application testifies to the eight months of intensive effort culminating in approval by the 41-member Regional Advisory Group on July 26, 1968.

"Operational Readiness" required concurrent development of the following four components:

A Responsible Grantee Organization

The law requires effective cooperative arrangements between the medical centers and peripheral health care organizations and personnel. Northlands Regional Medical Program was incorporated as a non-profit corporation on July 1. By-Laws were adopted on July 9. A "Guarantee of Support" of $10,000 was obtained from each of the nine sponsoring organizations to establish fiscal responsibility. The processes necessary to achieve these results were tedious and difficult. Like feminine charm, intimate performance is more difficult to achieve than overt appearance and pronouncement.

Effective Planning for Action

The law requires that component projects in the program be based on demonstration of needs, resources, objectives and priorities. This process required two steps—first, formulation of planning documents representing consensus opinions on planning for the program; and second, effective review and decision regarding a total of 22 projects which were proposed for inclusion. Twelve committees and sub-committees of five to seven men each (a total of 62 professional persons) spent a total of 117 man days in 29 meetings, varying in duration from one-half to two days, to carry out this component. The individual home study time and the many days of NRMP staff time represents significant, untabulated additional efforts. The committees were remarkably dedicated and conscientious in their deliberations. Project proposers were not given an opportunity to personally come before review committees, to avoid personal pressures. Like Judeo-Christianity, the idealism of health care institutions and personnel is put to the crucial test when funding of personal or institutional interests is concerned.

Effective Direction by the Board of Trustees

The success or failure of the corporation is ultimately determined by the effectiveness of its Board of Trustees. The Board of Northlands Regional Medical Program spent many long hours in development of the Articles of Incorporation, By-Laws, new Regional Advisory Group plus review of all project proposals.

The philosophy of Regional Medical Programs is new to all of us. Decision-making involves controversy. Continuing readjustment and self-renewal are required. As in marriage, partners on a Board are often the severest critics of each other.

Formation of and Approval by a "Regional Advisory Group"

The law requires "veto-type" power to be vested in an advisory committee representing all health care interests in the region. A new Regional Advisory Group of 41 voting and 15 non-voting members was created. By-Laws were formulated. Two all-day meetings were held on May 25 and July 26. Approval of the program on July 26 followed advance home review of some 800 pages of material and a long day of presentation of summaries. Some members were unhappy with the complexity and magnitude of the presentation compared to the time for discussion. Advisors are frequently called upon to help carry out the most difficult assignments in a minimum of time.

The operational grant application represents consensus agreements involving a total of 107 voluntary leaders in health care activities, a full-time staff of ten in the central organization and a part-time staff of five in the medical centers. One hundred and twenty-two leaders also constitute 122 critics. Consensus approval was a difficult but significant achievement. We believe the proposed program is a good one and we are proud to present it to the Division of Regional Medical Programs. The program contains the following:

1. Four Core Proposals for overall development and operation—Central Organization; University of Minnesota; Mayo Foundation; and American Rehabilitation Foundation.
2. Intensive Coronary Care Unit Project—Minnesota Heart Association, H. T. Mankin, M.D., Director.
3. Postgraduate Education in Pediatric Cardiology—University of Minnesota, R. V. Lucas, M.D., Director.
4. Education and Clinical Evaluation in Coronary Heart Disease—Mayo Clinic, R. C. Bahn, M.D., Director.
5. Diabetes Regional Center—Diabetes Research Foundation, D. D. Etzwiler, M.D.
6. Pilot Phase Regional Cancer Registry—Northlands Regional Medical Program, V A. Gilbertson, M.D., Director.
7. Stroke Rehabilitation Through Education—American Rehabilitation Foundation, J. A. Anderson, M.D., Director
8. Stroke Rehabilitation Management Simulator—American Rehabilitation Foundation, L. R. Leslie, M.D., Director.
9. Pilot Program of Continuing Medical Education—Mayo Clinic, C. F. Code, M.D.
10. Postgraduate Education in Diseases of Childhood—University of Minnesota, J A. Anderson, M.D., Director.
11. Dial-Access Medical Library—Northlands Regional Medical Program, L. G. Berglund, B.A., Director.
12. Planning Program for Heart, Cancer and Stroke—Saint Paul Bureau of Health. B. L. Levich, Director.

The application will now be subjected to intensive review by the Division of Regional Medical Programs. This will include a two to three-day site visit by a peer group team of leaders in health care fields. Final decision will rest with the National Advisory Council at its meeting on November 28.

Winston R. Miller, M.D., F.A.C.P.
Program Director

choose an experienced candidate—
millions of doses prescribed

Benadryl®
(diphenhydramine hydrochloride)

The White band on Pink capsule combination is a registered trademark of Parke, Davis & Company.

Supplied in various dosage forms including Kapseals, containing 50 mg. of diphenhydramine hydrochloride.

Parke, Davis & Company, Detroit, Michigan 48232

PARKE-DAVIS

When it's more than a bad cold

your patient can feel better while she's getting better

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In tetracycline-sensitive bacterial infection complicating respiratory allergy, ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Contraindications: Hypersensitivity to any component.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Drowsiness, anorexia, slight gastric distress can occur. In excessive drowsiness, consider longer dosage intervals. Persons on full dosage should not operate vehicles. Nonsusceptible organisms may overgrow; treat superinfection appropriately. Treat beta-hemolytic streptococcal infections at least 10 days to help prevent rheumatic fever or acute glomerulonephritis. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Adverse Reactions: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity* reactions—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

Lederle

Tenth Annual Methodist Hospital Symposium

The tenth annual symposium, sponsored by the Methodist Hospital medical staff, will be held on Saturday, September 14, 1968, in the Methodist Hospital auditorium.

The subject for this coming year's symposium will be on current concepts and treatment of "shock."

The Minnesota Academy of General Practice has approved this symposium for six prescribed hours of credit.

There is no registration fee for the scientific sessions or the noon luncheon. All physicians are most cordially invited to attend. For additional information please contact Mrs. Audrey Engstrom, medical staff secretary, 929-1313.

Sixth National Cancer Conference

Conference will be held September 18-20 in Denver, Colorado. For full information contact: American Cancer Society, 3702 E. Lake Street, Minneapolis. Phone 722-6614. Subjects to be discussed are cancer of the female pelvis, gastrointestinal tract, skin, neck and head, and lung. Also to be discussed are skeletal tumors, soft part tumors and basic problems and advances in cancer chemotherapy and hormone therapy.

(Continued from page 1302)

THE WEST MEDICAL CLINIC has an opening for a General Practice Physician, on October 1, 1968. This is a five man group that conducts a practice near downtown St. Paul and also, has the Airport Medical Clinic at Wold Chamberlain Field, Twin City International Airport. Both clinics have full laboratory and x-ray services with technologists covering both fields.

The Airport Medical Clinic does industrial, occupational and Aviation medicine. FAA examinations are conducted at both clinics.

The clinic located near downtown St. Paul has a practice limited principally to internal medicine, pediatrics, as well as occupational and industrial medicine. There is only a limited practice of obstetrics and no surgery.

Salary is open and opportunity for partnership is available. Write: West Medical Clinic, 539 W. Seventh Street, St. Paul, Minnesota 55102. Phone: Area Code 612-227-9341.

ANOKA-MINNEAPOLIS excellent openings for psychiatrist—unit chief & staff physicians. 600-bed open-door hospital. Salary $16-$28,500. Apply Medical Director, Anoka State Hospital, Anoka, Minnesota 55303.

DOCTOR WANTED in Fairfax, Minnesota. Clinic building available. Present doctor leaving. This is an excellent opportunity. Please contact Dr. Glenn Nelson or Leo Keller at Fairfax.

FOR SALE: Rarely used manual Ritter Multi-purpose proctoscopic table—Model 3—Type 7. Purchase price when new $1,400.00. Best offer takes table. Telephone Mrs. Asmus 645-1195 or write Mrs. Asmus at 393 North Dunlap Street, 231 Central Medical Bldg., St. Paul 55104.

PSYCHIATRIST—board eligible, desires association with individual or group in Twin Cities area. Eight years experience in general and forensic psychiatry. Write MINNESOTA MEDICINE-413, 375 Jackson St., St. Paul 55101.

FAMILY PHYSICIAN wanted for an association with a clinic in the Minneapolis suburban area. Excellent hospital, school, churches, and living facilities available. Write Drs. T. J. Bloedel and H. R. Ransom, 226 Central Ave., Osseo, Minnesota, or telephone 425-2118 collect.

TWO MAN GROUP needs a third general practitioner in a fast-growing West St. Paul area. Begin with salary and assume early partnership. Contact N. W. Howe, M.D., or E. J. McEllistrem, M.D., 1246 Gorman—West St. Paul. Minn. 55118 Telephone: 224-8001.

WANTED: Physician for ward and/or clinic in accredited State Mental Hospital in fishing and hunting area of Minnesota. Should have interest though not necessarily experience in mental health and illness. Living quarters provided. Send vita with application. Not a retirement position. Older physicians with good credentials acceptable. Write: MINNESOTA MEDICINE-414, 375 Jackson St., St. Paul 55101.

DESIRE TO GIVE away a general surgery practice which should immediately provide a versatile surgeon with 200 majors annually and unlimited ceiling. Will provide modern office facilities in a ten-year-old clinic building and guarantee a minimum income with no strings attached. Should be board qualified and under forty-five. Excellent hospital facilities with resident anesthesiologist and pathologist. Reason:—desire to limit my practice to Urology. Write or call O. K. Behr, M.D., 407 North Broadway, Crookston, Minnesota—Area Code 218-281-3210.

WANTED BY TWO INTERNISTS—a Board Eligible or Board Certified Internist to practice in the Twin City area. Excellent opportunity and early partnership. Write: MINNESOTA MEDICINE-407, 375 Jackson, St. Paul, 55101.

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55102.

FOR RENT: 14-room deluxe clinic in shopping center—Robbinsdale. 5 min. from Glenwood Hills and No. Memorial Hospitals—3 months rent free—will subdivide—36th Ave. No. and Noble—Noble Drug, JU 8-9449—Ben or Lou.

EIGHTEEN-MAN Wisconsin group located in college community of 40,000 with excellent hospital facilities is seeking additional associates in the following areas: (1) Internal Medicine, (2) Urology, (3) General Surgery, (4) General Practice, and (5) Pediatrics. For further information please contact D. R. Griffith, M.D., Midelfort Clinic, Eau Claire, Wisconsin 54701.

ASSOCIATE urgently needed in busy general practice. Excellent clinic and hospital facilities. Salary open. Partnership after 1 year. Klefstad Clinic, Greenbush, Minn. Call collect: Lloyd H. Klefstad, M.D., Tele. 218-782-5275 or 4725.

Heart Symposium

"Cardiovascular Disease—Practice, Problems, Progress" is the theme of a two day Great Plains Heart Associations Symposium, to be held at the Sheraton-Ritz Hotel in Minneapolis on Friday, September 27, and Saturday, September 28, 1968. Host State for the Symposium will be the Minnesota Heart Association. There will be Curbside Sessions on specialized techniques, remedial heart disease, hypertension, diagnosis and management of stroke, cardiovascular drugs, and pulmonary embolism: diagnosis, medical and surgical management. Attendees are encouraged to bring along electrocardiograms for discussion. For more information contact the Minnesota Heart Association, 1821 University Ave, St. Paul.

Sources of sinus headache

REGION OF SENSATION

FRONTAL SINUS—headache localized over the frontal region, commonly beginning in the morning. Eyes painful to touch, may be slight swelling over eyes, puffy eyelids.

SPHENOID SINUS—most difficult to diagnose. Headache or sense of pressure over vertex. May be pain in ear or mastoid region.

MAXILLARY SINUS—headache and tenderness under eyes at top of cheekbones, usually starting in early afternoon. Possible swelling of cheek. Pain in jaw and back teeth.

ETHMOID SINUS—headache, tightness in upper part of bridge of nose and well down its sides. Pain, deep-seated behind the eyes and in inner corners of the eyes.

TURBINATES—pain along medial and lateral walls of the inside of the nose. Headache in frontal region, along supraorbital ridge, a feeling of fullness in the head.

Source of symptomatic relief

SINUTAB

Sinus headache is often a reflection of congestion in the nasal mucosa. The pain that results in the various regions of the head may help in determining the particular structure(s) responsible. The Sinutab formula is specifically designed for symptomatic relief of sinus headache and nasal congestion. **Sinutab** *not only* **provides an effective decongestant** — to reduce mucosal engorgement and facilitate freer breathing — *and* **an antihistamine** — to help reduce edema and excessive secretions — but it *also* provides, in contrast to other leading decongestants, **two analgesics** for immediate relief of pain and discomfort.

And, too, the Sinutab dosage schedule of 2 tablets, *q.* 4 *h.* permits controlled and continuing analgesic relief.

Adverse Reactions: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive or operate machinery if drowsiness occurs. Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

Each tablet contains 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

SPECIFIC FORMULA **SINUTAB**® FOR SINUS HEADACHE

Also Available on Prescription:

Sinutab® with Codeine.* Each tablet contains 15 mg. (¼ gr.) codeine phosphate (Warning: May be habit forming), 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

Sinutab® Pediatric Suspension. Each 5 ml. teaspoonful contains 300 mg. acetaminophen, 12.5 mg. phenylpropanolamine HCl, and 10 mg. phenyltoloxamine citrate.

*Subject to Federal Narcotics Regulations.

For 1 complimentary bottle of 30 Sinutab tablets, write: J. S. Travis, Warner-Chilcott Laboratories, Morris Plains, N.J. 07950. Please mention this journal.

Physician's Diary

It's the daily grind that gives a man polish.—National Safety News

Doctors Paul G. Quie, Robert A. Good, Justin J. Wolfson, Stefan D. Laxdal, Hans Kuisk, Jose B. Sanchez, Stephen A. Kieffer, Kirt Amplatz, Harold O. Peterson and **Yosh Maruyama** presented medical papers to the Radiological Society of North America, which held its annual meeting in Chicago recently.

* * *

Dr. John E. Smith, Edina, has been elected president of the St. Barnabas Hospital Medical Staff.

* * *

Dr. T. G. Martens, Mayo Clinic ophthalmologist and otolaryngologist, is the newly elected president of the Minnesota Academy of Ophthalmology and Otolaryngology. He will take over the office January 1, 1969.

* * *

After retiring from private practice in St. James on May 1, **Dr. A. D. Mattson** is with the Minnesota Department of Welfare in the reorganization of the staff at Faribault State Hospital.

* * *

Dr. Kristofer Hagen, Edina, served in South Vietnam for two months with the American Medical Association Volunteer Physicians for Vietnam.

* * *

Dr. Jeannette L. Baker has been named to succeed **Dr. W. L. Patterson** as medical director of the Fergus Falls State Hospital.

* * *

Dr. Edward Mandell, Director of the Veterans Administration Hospital, Minneapolis, retired recently.

* * *

Newly elected officers of the Minnesota Academy of General Practice are **Dr. Matt Plasha,** Coon Rapids, president, **Dr. Wallace Mathews,** Mankato, president-elect, **Dr. John W. Lester,** Mapleton, vice-president and chairman of the board of directors, and **Dr. C. A. Anderson,** Hector, secretary-treasurer.

* * *

Dr. Tracy E. Barber, Austin, has been named treasurer of the Industrial Medical Association, international association of physicians of industry.

New Locations: **Dr. L. J. Hoyer** has left Windom to take a position in the general medical and surgical department of the Winnebago State Hospital in Winnebago, Wisconsin. . . . **Dr. Kent Hardy,** Mayo Graduate School resident in dermatology, has served in Afghanistan for three months with MEDICO, a service of CARE. . . . **Dr. John Mathers,** now at the Austin Clinic, began a sabbatical leave of one or two years in July to become teacher and consultant in the Department of Obstetrics and Gynecology in the Okinawa and Central Hospital near Naha, Okinawa. . . . **Dr. Robert L. Hegrenes** will leave Farmington to join the Hutchinson Medical Center in Hutchinson. . . . **Dr. Benigno Buentipo** will begin practice in Wheaton. . . . **Dr. Ben M. Tuma,** formerly of Montgomery, has joined the Alexandria Clinic. . . . **Dr. Curtis A. Johnson** has left Waseca to join **Dr. George Bingham** in Olivia where a new clinic is to be completed. . . . **Dr. Martin Raymond Swersky** will become a medical officer of the U.S. Public Health Service Indian Hospital in Cass Lake.

* * *

Several Minnesota physicians have been named by the American Academy of Pediatrics to evaluate the medical aspects of Head Start Programs. They are **Drs. Albertus F. Dodson,** Brainerd, **Robert Hodapp,** Willmar, **David Bloom,** Golden Valley, **Curtis M. Johnson,** Winona, and **Edmund Burke,** Rochester.

* * *

The second Pioneer Award of the Northwestern Mental Health Center was presented to **Dr. Clifford Stadem,** Crookston, former chairman of the Mental Health Center Board. The award was presented in appreciation for his continued guidance to the Mental Health Board.

* * *

Richard O. Zocher has been appointed Administrator of St. Croixdale Hospital, Inc., in Prescott, Wisconsin. Prior to his appointment, Mr. Zocher was associated with Mounds Park Hospital in St. Paul for eight years as Business Manager.

Tandearil® in Osteoarthritis
oxyphenbutazone

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.
Warning: Tandearil is an analog of phenylbutazone; sensitive patients may be cross-reactive. If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Persistent or severe dyspepsia may indicate peptic ulcer; perform upper gastrointestinal x-ray diagnostic tests if drug is continued. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with caution in the first trimester of pregnancy and in patients with thyroid disease.
Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia), sudden weight gain (water retention), skin reactions, black or tarry stools or other evidence of intestinal hemorrhage occur. Make complete blood counts at weekly intervals during early therapy and at 2-week intervals thereafter. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.
Adverse Reactions: The more common are nausea and edema. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension, the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reacti-

"Pain Break" for an osteoarthritic.

Tandearil can usually ease it.

At 46, her knees still look good on the outside. But inside, there may be the familiar picture of osteoarthritis.

If aspirin doesn't help, Tandearil often will. Pain and stiffness begin to ease up in 3 or 4 days. You can often maintain response with a daily dose of only 1 or 2 tablets.

Of course, Tandearil is not for every osteoarthritic. Select your patients carefully and follow them in line with the Contraindications, Precautions, Warning, and Adverse Reactions listed below.

But for many aspirin-stubborn osteoarthritics, let Tandearil ease the unwelcome pain breaks of osteoarthritis.

Tandearil®
oxyphenbutazone

vate a latent peptic ulcer. The patient should be instructed to take doses immediately after meals or with milk to minimize gastric upset. Drug rash occasionally occurs. If it does, promptly discontinue the drug. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis) or a generalized allergic reaction similar to a serum sickness syndrome may occur and require permanent withdrawal of medication. Agranulocytosis can occur suddenly in spite of regular, repeated normal white counts. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, hypersensitivity, angiitis, pericarditis and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

For complete details, please see full Prescribing Information.

Dosage in Osteoarthritis: Initial: 3 to 6 tablets daily in divided doses. Usually unnecessary to exceed 4 tablets daily. A trial period of one week is considered adequate to determine the therapeutic effect of the drug. Maintenance: Effective level often achieved with 1 or 2 tablets daily, should not exceed 4 tablets daily. In selecting appropriate dosage in any specific case, consideration should be given to the patient's weight, general health, age and other factors influencing drug response. Availability: Tan, round, sugar-coated tablets of 100 mg. in bottles of 100 and 1000.

Sources of Sinus Headache

Sinus headache is often a reflection of congestion in the nasal mucosa. The pain that results in the various regions of the head may help in determining the particular structure(s) responsible. The proved formula of Sinutab which provides triple action — analgesic, decongestant and antihistaminic — is specifically designed for the symptomatic relief of sinus headache and nasal congestion.

INDICATIONS: Sinutab is indicated for the symptomatic relief of headache, facial pain, malaise, fever, nasal and sinus congestion often associated with acute and chronic sinusitis, allergic rhinitis, vasomotor rhinitis, influenza, and the common cold.

ADVERSE REACTIONS: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

PRECAUTIONS: Instruct patients not to drive or operate machinery if drowsiness occurs. Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

DOSAGE: Adults — 2 tablets every 4 hours.
Children (6-12 years) — ½ the adult dose.

Each tablet contains 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

Source of Symptomatic Relief

Sinutab® | 2 tabs. q.4h.

■ **to help restore and stabilize the intestinal flora**

■ **for fever blisters and canker sores of herpetic origin**

LACTINEX contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

First introduced to help restore the flora of the intestinal tract in infants and adults,[1, 2, 3, 4] LACTINEX has also been shown to be useful in the treatment of fever blisters and canker sores of herpetic origin.[5, 6, 7, 8]

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

Today's physician sees more on NCME TV...

BETTMANN ARCHIVE

The first nationwide medical television service, NCME—The Network for Continuing Medical Education—brings you visually the important achievements of leading medical authorities. By means of closed-circuit television, this independent network provides your hospital or medical school with a complete videotape service that helps shorten the gap between new medical knowledge and its availability for clinical or teaching purposes.

NCME
The Network for Continuing Medical Education

NCME TV Offers These Practical Benefits:

☐ Every two weeks a new 60-minute videotape dealing with three separate medical subjects is sent to participating institutions.

☐ Content and format of NCME telecasts fulfill criteria for postgraduate medical education, permitting American Academy of General Practice course credits under specified conditions.

☐ To help your institution make effective use of closed-circuit television, NCME offers a wide range of services and utilization aids, including: Technical consultation in setting up a closed-circuit system; advance program information on the contents of each telecast; display units to help publicize programs; expense-paid seminars to improve utilization of medical television.

☐ NCME programs are brief and may be shown as often as desired; you can view the telecasts at times that are most convenient, without disrupting your normal schedule.

☐ Frequently NCME makes available published papers related to subjects presented on closed-circuit television.

A recent NCME hospital telecast presented Philip N. Sawyer, M.D., Professor of Surgery and Head of the Vascular Surgical Service at Downstate Medical Center, Brooklyn, N.Y., in a demonstration and evaluation of "Gas Endarterectomy."

In this program, Dr. Sawyer performs the operation on a patient with gross occlusion of the right iliac, femoral and popliteal arteries.

In Dr. Sawyer's view, gas endarterectomy has several advantages over mechanical methods: the operation can be completed faster, causes less damage to the arteries and offers a more successful outcome.

NCME is an independent network supported by Roche Laboratories to increase the use of closed-circuit TV for medical education under direct hospital and school control.

If your hospital or school does not participate in the biweekly NCME program, information on the cost-free service may be obtained by writing to NCME, 342 Madison Avenue New York, N.Y. 10017

"All Registered Nurses are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards. Therefore, all registered nurses are alike.

That's nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all registered nurses aren't alike, either.

My Political Creed

I am a free citizen in a free nation.

Whoever diminishes my freedom as an individual diminishes the sum total of freedom in my country.

I am also a physician, free thus far to treat my patients to the best of my ability.

Abridge that freedom and the health of my patients is adversely affected.

These things being true, I cannot -- I will not -- stand idly by when these hard-won freedoms are under attack.

For I believe that the values upon which this country was founded are immutable and have not been eroded by the passage of years.

I believe that I, as a free citizen in a free land, am obligated to defend my beliefs in the ways permitted to me, and required of me, by our form of government.

Therefore, let no man seek to bar me from the political process; for it would be akin to denying my right to participate in the process that determines free government.

President's Letter

YEARS AGO AN unknown writer described four sorts of readers: "Sponges which attract all without distinguishing; Howre-glasses which receive and powre out as fast; Bagges which only retain the dregges of the spices and let the wine escape, and Sives which retaine the best onely."

Once again we are in an election year—this time the quadrennial extravaganza of presidential selection. Now, if ever, physicians must rise to the challenge to make the next Congress aware of and responsive to the problems and needs of American medicine. Already, more than a thousand medically-oriented bills have been introduced into the Congress. As enunciated by Carlyle, "Our duty is not to see what lies dimly at a distance, but to do what lies clearly at hand."

What, then, can we do? Of course, each of us must himself vote for the candidates of his choice. We must wield our not inconsiderable (and underrated) influence in the area of politics ("the affairs or activities of those who are engaged in controlling or seeking to control a government or its offices or departments"). We must contribute time wrung from our busy hours and moneys to support inescapably expensive campaigns.

Special note might here be made regarding the American Medical Political Action Committee (AMPAC) and our state component organization, the Minnesota Medical Political Action Committee (MINNPAC). Lest this latter designation be unfamiliar, let me remind you that it is the successor to NUHOPE, which Dr. James Blake founded and shepherded so well for so many years. The newly-named unit is under the experienced and enthusiastic direction of Dr. Richard Engwall. He would welcome your support, be it in time or moneys or both.

Sir William Osler has stated, "By far the most dangerous foe we have to fight is apathy—indifference from whatever cause, not from lack of knowledge, but from carelessness, from absorption in other pursuits, from a contempt bred of self-satisfaction." He said further, "The word of action is stronger than the word of speech."

May you readers be "Sives."

It's almost as if you were there to give an injection of penicillin

dependable oral penicillin therapy V-Cillin K®, Pediatric

Potassium Phenoxymethyl Penicillin

Description: V-Cillin K, the potassium salt of V-Cillin® (phenoxymethyl penicillin, Lilly), combines acid stability with immediate solubility and rapid absorption. Higher, more rapid serum levels are obtained than with equal oral doses of penicillin G.

Indications: Streptococcus, pneumococcus, and gonococcus infections; infections caused by sensitive strains of staphylococci; prophylaxis of streptococcus infections in patients with a history of rheumatic fever; and prevention of bacterial endocarditis after tonsillectomy and tooth extraction in patients with a history of rheumatic fever or congenital heart disease.

Contraindication: Penicillin hypersensitivity.

Warnings: In rare instances, penicillin may cause acute anaphylaxis which may prove fatal unless promptly controlled. This type of reaction appears more frequently in patients with a history of sensitivity reactions to penicillin or with bronchial asthma or other allergies. Resuscitative drugs should be readily available. These include epinephrine and pressor drugs (as well as oxygen for inhalation) for immediate allergic manifestations and antihistamines and corticosteroids for delayed effects.

Precautions: Use cautiously, if at all, in a patient with a strongly positive history of allergy.

In prolonged therapy with penicillin, and particularly with high parenteral dosage schedules, frequent evaluation of the renal and hematopoietic systems is recommended.

In suspected staphylococcus infections, proper laboratory studies (including sensitivity tests) should be performed.

The use of penicillin may be associated with the overgrowth of penicillin-insensitive organisms. In such cases, discontinue administration and take appropriate measures.

Adverse Reactions: Although serious allergic reactions are much less common with oral penicillin than with intramuscular forms, manifestations of penicillin allergy may occur.

Penicillin is a substance of low toxicity, but it possesses a significant index of sensitization. The following hypersensitivity reactions have been reported: skin rashes ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; and reactions resembling serum sickness, including chills, fever, edema, arthralgia, and prostration. Severe and often fatal anaphylaxis has occurred (*see* Warnings). Hemolytic anemia, leukopenia, thrombocytopenia, and nephropathy are rarely observed side-effects and are usually associated with high parenteral dosage.

Administration and Dosage: Usual dosage range, 125 mg. (200,000 units) three times a day to 500 mg. (800,000 units) every four hours. For infants, 50 mg. per Kg. per day divided into three doses.

See package literature for detailed dosage instructions for prophylaxis of streptococcus infections, surgery, gonorrhea, and severe infections.

How Supplied: Tablets V-Cillin K® (Potassium Phenoxymethyl Penicillin Tablets, U.S.P.), 125 mg. (200,000 units), 250 mg. (400,000 units), and 500 mg. (800,000 units).

V-Cillin K® (potassium phenoxymethyl penicillin, Lilly), Pediatric, for Oral Solution, 125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc. of solution (approximately one teaspoonful). [042567A] 800197

Adenomammectomy

Origin and Technique

CARL O. RICE, M.D.
Minneapolis, Minnesota

THE TERM "ADENOMAMMECTOMY" was first described in 1951.[1] It was derived from the Greek prefix "adeno" denoting a gland, the Latin "mamma" for breast, and the Greek "ektome" meaning excision of. Perhaps adenomastectomy would have been etymologically more correct, being then all of Greek derivation. But for a procedure designed to preserve cosmetic contour, adenomammectomy seemed linguistically softer and more euphonious.

A radiating incision for breast biopsy of a benign lesion is inadequate because it does not allow an opportunity to visualize any other portion of the breast than that which can be seen in the depth of the incision. The finger or instrument that has removed the lesion has done scarcely more than a grubbing procedure. It is a dangerous incision for the biopsy of a malignant lesion because the mechanical trauma that is inflicted in the vicinity of carcinomatous tissue may tend to disseminate the lesion rather than confine it.

An elliptical excision for biopsy, though somewhat neater surgically, has the same disadvantages as the radiating incision; in addition it will have contributed unnecessarily to disfigurement of the breast contour if the lesion is found to be benign. For a malignant lesion, if the biopsy is truly excisional, it will have served its purpose as an initial step toward radical mastectomy.[2]

Simple mastectomy for a benign lesion is mutilating, irretrievable and wholly unnecessary; for a malignant lesion it is inadequate except as a temporizing procedure; and it can never be considered a cure for cancer.

Surmounting the Pitfalls

Early in the development of this procedure a number of undesirable sequelae were encountered which, as they were obviated, made it possible to improve the technique as well as the end result. In order that these pitfalls might be avoided by other surgeons they are detailed in the following paragraphs.

Posterior Excision of a Lesion

In 1949 a mammary thoracic fold incision was being used[1] for the purpose of excising suspected benign tumors within the breast substance. In this procedure the breast was separated from the pectoral fascia to the point at which the lesion had been palpated, and the specific mass was then elliptically excised from the posterior surface of the breast.

During this operation multiple cysts or other lesions not palpated on clinical examination were almost universally encountered. This led to more extensive excision of breast substance from the posterior surface in an effort to eliminate the development of subsequent clinically palpable cysts which would require still another operation. Furthermore, if only the clinically palpable mass was removed and the uninvolved breast substance allowed to remain, the contour of the breast was not as smooth as seemed desirable because the excised tissue left a palpable crevasse covered with skin.

Allowing irregular masses of uninvolved breast substance to remain produced undesirable irregularities of contour.

Partial Adenomastectomy

A more extensive partial adenomastectomy was instituted in 1950; but because a portion of breast substance was left at the upper limit, (See inset, Figure 1) the remaining 1-cm ridge of breast tissue left the patient with a palpable cleft at the upper margin of the brassiere line. This too seemed undesirable as it often perplexed the patient who could palpate the ridge and presumed that it was tumor tissue that had not been completely removed.

Subcutaneous Mastectomy

Removal of all of the breast substance and an extension of the dissection of the gland into the subcutaneous fat was then done; but when this flap of redundant skin and subcutaneous tissue healed to the pectoral fascia, even though enough breast skin and subcutaneous adipose tissue remained to produce a redundant overhang, the cosmetic appearance was puckered and unsightly, leaving an uneven plowed look to the surface of the breast, with the overhanging redundancy constituting nothing more than a purse-like flap of skin.

Dissecting through the subcutaneous fat

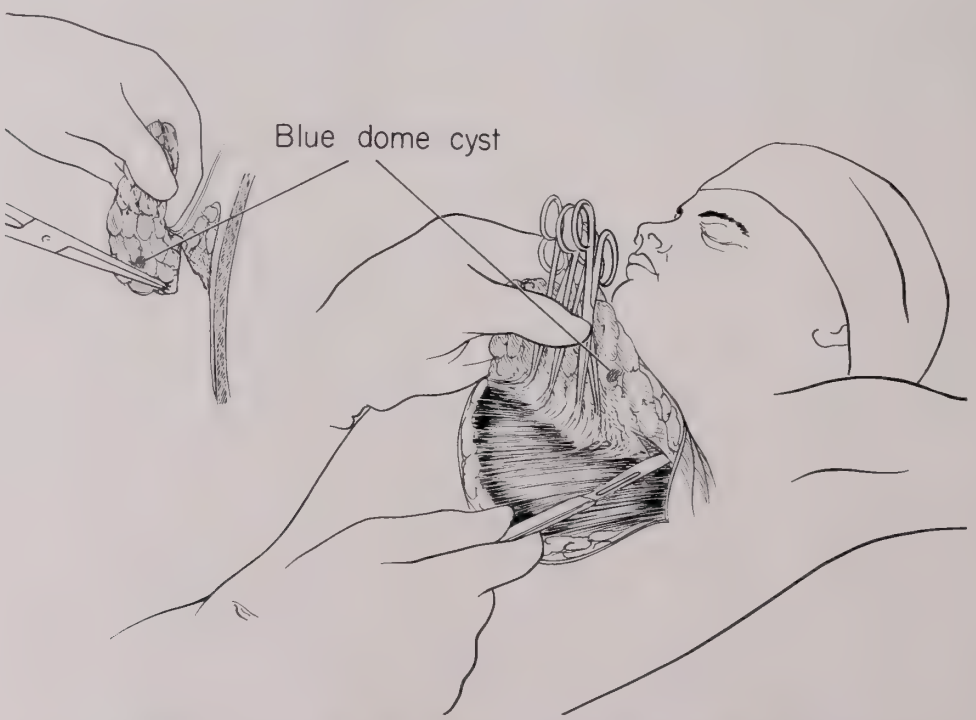

Fig. 1—Through a curved mammary thoracic fold incision the dissection off the pectoral fascia has been made to the upper limits of the breast substance. The row of Ochsner forceps at the upper margin of the everted breast substance has been placed and the incision has been started through the gland (see inset).

sometimes left a compromised circulation to the overlying skin, occasionally resulting in small areas of necrosis.

Endeavoring to eliminate the overhanging flap by excising an ellipse of skin from the apparent abundance of skin lying between the nipple and the mammary thoracic fold left the patient with a nipple turned underneath and no improvement in the contour.

Subtotal Adenomammectomy

Realizing that there is a layer of areolar elastic tissue between the breast substance and the subcutaneous fat, our next design was to leave a two-millimeter layer of "breast capsule" in the hope that the contour could be preserved. This did prove to be the case and resulted in adenomammectomy as shall be described in detail in the following paragraphs.

In 1950 the term adenomammectomy was adopted and with this procedure we have continued to remain content.

The Technique of Adenomammectomy

Lest the surgeon become discouraged while in the process of learning the pitfalls that have been encountered in the development of this procedure, the details of the technique are here described minutely.

The Incision

The curved incision is made directly in the mammary thoracic fold with a sharp scalpel and should be generous enough so that when the breast substance has been dissected off the pectoral muscle, the entire glandular area of the breast can be everted* and exposed to direct vision and palpation.

Healing of this mammary thoracic fold incision leaves an invisible scar after six months, whereas a differently placed incision either above or below, though not a serious objection, does leave a more visible scar. One of the dictums in plastic surgery is that of placing the incision in the normal folds of the skin.

Only when the findings indicate that a radical mastectomy is the most likely procedure, is a somewhat higher-positioned incision made, so as to be able to take advantage of the additional skin available at that point and allow closure of the elliptical defect which has been left after radical mastectomy has been performed.

*See Test Your Word Score Page 1367.

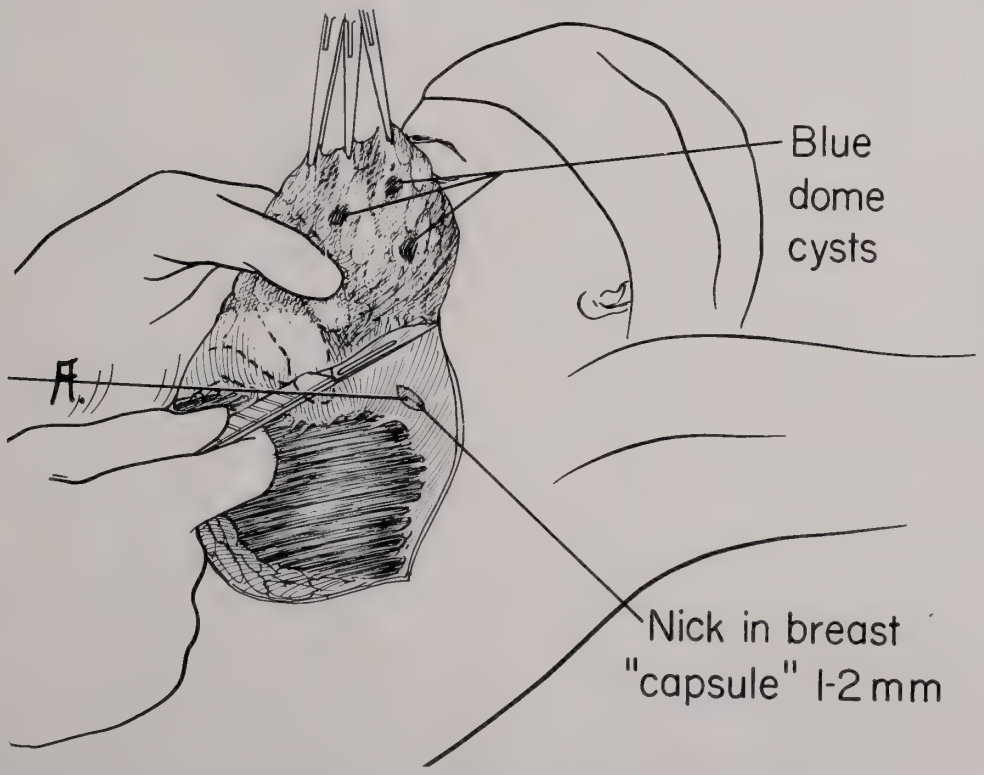

Fig. 2—The dissection of the breast substance from the breast flap has progressed and a niche in the breast capsule has been made to identify the depth of the capsule.

Dissection from the Pectoral Fascia

The skin incision extends directly to the areolar plane between the breast substance and the pectoral fascia lying upon the pectoral muscle. In this plane of cleavage the dissection is continued cephalad to the upper limits of the breast substance. This is best accomplished by holding the breast in the palm of the left hand as the surgeon palpates the upper margin of the breast substance between his fingers, lying upon the skin surface, and his thumb, placed against the under surface of the breast (Figure 2).

This dissection is made with the endotherm knife which, as it progresses through the areolar plane between the breast substance and the pectoral fascia, cauterizes the major portion of the small vessels and eliminates a considerable quantum of the bleeding. Other vessels are meticulously clamped with narrow pointed Rankin clamps. These bleeding points are coagulated with pinpoint precision by the endotherm in order to diminish, as much as possible, the burned tissue.

Turning the Breast Inside Out

It is now possible for the surgeon to evert the breast in order to visualize and palpate any portion of the breast substance from its back side, often revealing blue dome cysts or dilated ducts which were not clinically palpable before. Fibrous plaques or discrete tumors are easily felt between the palpating fingers and the thumb.

At this point in the procedure all of the breast substance which is to be removed now lies in the palm of the left hand along with its overlying skin and subcutaneous fat. The rounded contour of the breast is turned inside out, and the dissection of the breast substance, leaving a thin capsule, follows the rounded hemisphere of the everted breast (Figure 3).

Placement of Forceps on Breast Substance

A row of four or five Ochsner forceps is placed along the upper margin of the everted breast substance (Figure 1) with their handles matched to facilitate their wielding. They are held in the surgeon's palm along with the everted breast; and gentle tension is exerted upon this row of forceps everting the breast substance as it is being dissected.

Excising the Breast Substance

An incision is then made, with a sharp scalpel, through the upper margin of the breast substance (Figure 1 inset). As the subcutaneously situated "breast capsule" is encountered, the meticulous shaving of the breast substance follows as closely as possible the rounded and everted "breast capsule."

One or two millimeters of breast capsule must be allowed to remain with the subcutaneous fat. The stereognostic palpating fingers which are everting the breast substance are the guide to this point of excision. If the surgeon cannot be certain with regard to the depth of the remaining "breast capsule" he may make a small niche through it until the larger lobulations of subcutaneous fat identify the depth of the capsule.

The dissection continues distally along the everted curve of the breast as the row of Ochs-

Fig. 3—The line of dissection of the breast from the pectoral fascia is indicated by the arrow, and the curved portion of the arrow indicates the dissection of the breast substance from the breast flap—leaving a 2-millimeter layer of breast capsule.

ner forceps is placed on tension so as to keep the breast substance constantly everted for clear visualization of the dissection as it progresses (Figures 2 and 3). There is no blind dissection at any point.

The endotherm knife is not used for this dissection of the breast capsule lest it inadvertently penetrate too close to the under surface of the adjacent skin, thereby causing a burn, with areas of subsequent necrosis.

Bleeding points are meticulously clamped with sharp-pointed Kelly or Rankin forceps.

In the process of progressing distally from above, one encounters the areola and nipple area, carefully cutting across the collecting ducts, but fastidiously avoiding the nipple itself, lest damage to the nipple cause impairment of its circulation and subsequent necrosis.

Having passed the lower border of the areola the dissection is almost completed but is continued in the same manner to the margin of the incision.

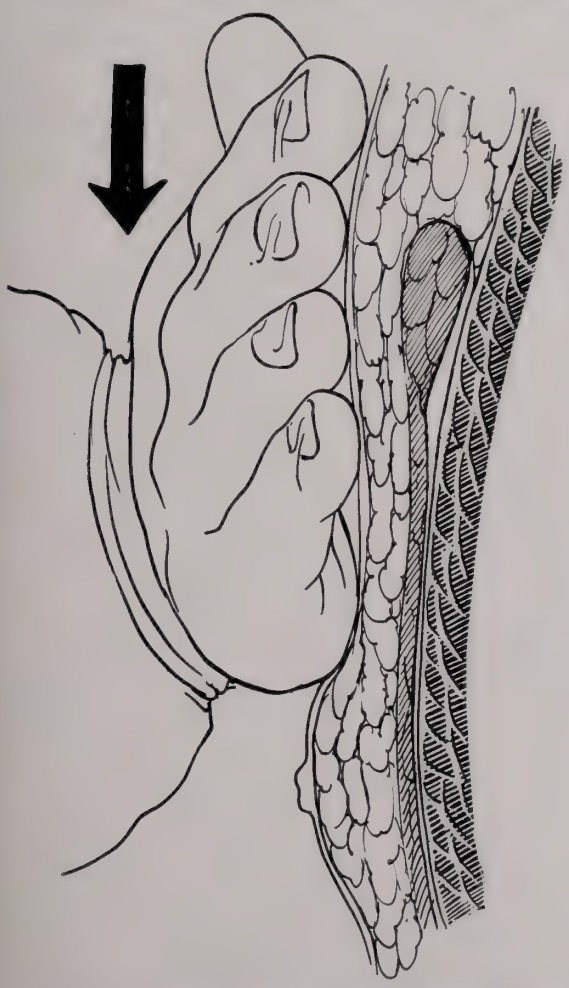

Fig. 4—The moist, palpating, gloved hand is passed from above downward over the breast flap to identify any irregularities that might require additional removal as demonstrated in Figure 5.

Controlling the Bleeding

The glandular substance of the breast has now been removed and a one-millimeter layer of breast capsule has been allowed to remain along with the subcutaneous fat, for cosmetic restoration: a very important detail of this operation.

During the dissection of the breast gland all bleeding points of any consequence are clamped with a Kelly forceps and subsequently cauterized with the point of the endotherm blade. However, one must avoid ironing the cut surface with the coagulating blade as this increases the area of burned tissue and consequently the postoperative exudate. This coagulation of the pinpoint bleeders must be done meticulously almost to the point of ennui. Caution with regard to the heat of the coagulator must be observed lest the heat penetrate and burn the under surface of the skin, to cause subsequent necrosis. The cut surface of the breast capsule must be absolutely dry. Warm packs, Gelusil, coagulating sponges, pressure, all contribute their bit; but the time consumed in waiting for the coagulating effects of these mechanisms is no greater than that expended in using meticulous pinpoint cautery with the endotherm. No further portion of the operation must be carried out until this control of the minute bleeding points has been completed. To allow *any* bleeding to remain defeats the primary adherence of breast substance to the pectoral fascia and will cause the breast flap to float upon the fascia in a pool of bloody exudate.

Re-evaluation of the Removed Breast Substance

In order to evaluate the removal of the proper amount of breast substance and the uniformity of its removal, the breast flap, after having been throughly controlled of its minor bleeding, is replaced on the chest wall. The moist palpating gloved hand is then passed from above downward over the breast flap. Any irregularities, ridges, or excessive amounts of breast capsule are readily palpated with the flat, moist, gloved hand (Figure 4). Palpating with a dry, bloody or sticky rubber glove or with the fingertips will not allow for accurate

interpretation.

The most commonly encountered irregularity is a small cleft of breast substance that has been left behind at the upper margin where the excision of the breast substance was started (Figures 1 and 5 inset). This and other irregularities produced by leaving an excessively thick portion of breast capsule can be removed with a curved shears until the palpating moist hand reveals a smooth contour from top to bottom (Figure 4). The remaining breast capsule should be uniformly two millimeters thick.

After these excessive and unevenly removed portions of breast capsule have been properly removed and the contour is smooth, minor bleeding points are re-evaluated, searched for and cauterized. No ties of any kind are used to control the bleeding points. To use ties produces more exudate than is produced by the meticulous pinpoint cautery.

Closing the Incision

Only after the field of excision is completely dry, two large, non-collapsible catheters are placed under the breast flap and brought out through a tight stab wound one inch below the lateral portion of the excision. These are anchored and held in position with a Japanese finger cot stitch and the catheters attached to continuous suction so as to keep the small amount of exudate from accumulating under the breast flap.

The two catheters are attached to a Y and then to active suction, which keeps the breast flap adherent to the pectoral fascia and eliminates the accumulation of small amounts of exudate which, if allowed to accumulate, will prevent primary healing of the raw surface to the pectoral fascia.

The skin is then closed with interrupted everting stitches of dermal and interspersed clips.

The Dressing

A one-strip Telfa dressing is placed across the line of incision, but no strapping of any kind is allowed across the breast in any area, as the pressure of a strapping will cause a ridge as the healing tissues adhere to one another.

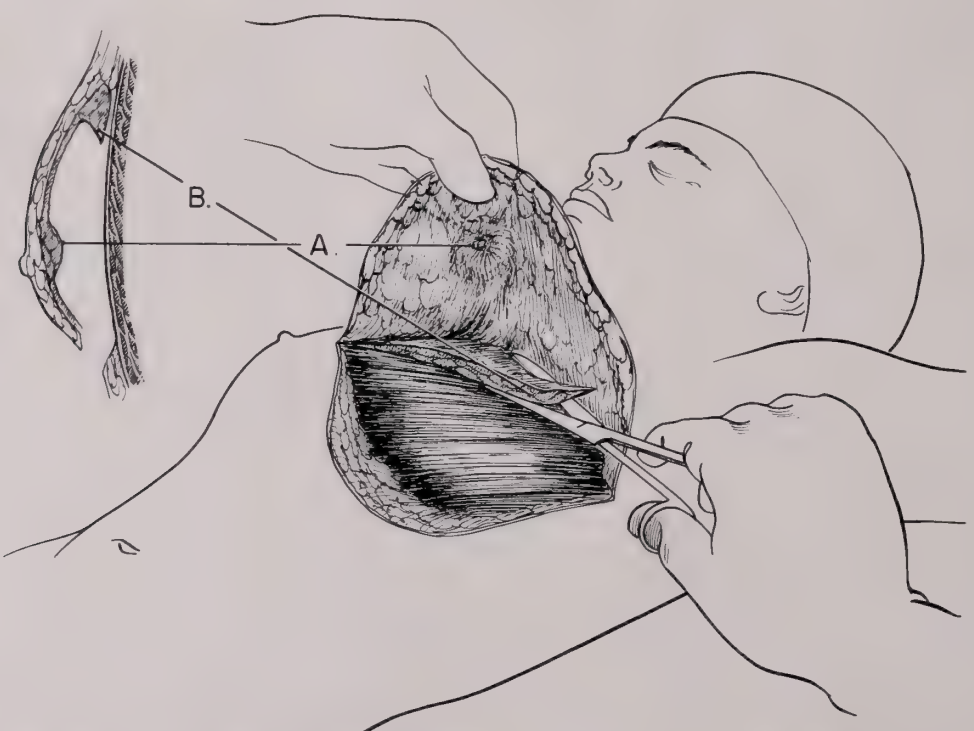

Fig. 5—Clipping away irregularities produced by leaving an excessively thick portion of breast capsule at any point is demonstrated (A and B). The remaining capsule must be uniformly 2-3 millimeters in thickness. Palpating the breast flap as demonstrated in Figure 4 will reveal these irregularities. All of the subcutaneous fat and the "breast capsule" remains with the breast flap. The skin edges are approximated with interrupted stitches and interspersed clips. No subcutaneous or other sutures are used.

Fashioning the Contour of the Breast

After the operation is completed and the dressings applied, the patient is placed in a semi-upright position so as to allow the normal redundant sag of the breast over the line of incision. If the operation has been meticulously done this positioning of the breast allows it to heal and develop a normal contour somewhat smaller than the contralateral breast, but in no instance a flat, male-type contour.

If there has been an inadvertent removal of the breast capsule over a small area, no attempt is made to re-approximate these edges of the capsule, as to do so will only add to the irregularity of the healing. If large plaques of breast capsule have been inadvertently removed, the breast contour will be distorted at that point.

No refashioning of the nipple or the areola is carried out, as this area will assume its normal position if the operation has been properly performed.

In the event of an inverted nipple existing prior to the operation, this can be corrected by taking a purse-string suture around the nipple from the outside, holding the nipple in the everted position.

Conclusions

Adenomammectomy is a completely satisfactory procedure for all breast biopsies.

Adenomammectomy provides a cure for fibrocystic disease, duct ectasia, fibrous plaques, and mastodynia from fibrous or cystic mastitis.

Adenomammectomy leaves a normal breast contour, though a somewhat smaller one.

Too Tough To Die

Cowboys sat tall and were too tough to die. At least so it would seem, judging from the memoirs of doctors who practiced among the ranches of the Old West. Take the eastern Oregon bunch grasser named Bill, whose horse kicked him in the forehead, right beneath his shaggy hairline. The hoof stripped a three-inch piece of scalp clean from the skull all the way from his forehead to the back of his head.

Bill tied the strip of flesh back in place with a red bandanna and rode 18 miles through sub-freezing weather to Farewell Bend. Blood ran down over his eyes and froze in cakes on his face. He strode into Dr. Urling Coe's house.

"Sew up this goddam fool head o' mine, Doc," he drawled, "'fore all them damn little brains o' mine falls out."

Dr. Coe cleaned and shaved the cowpuncher's head and put in 30 stitches while the cowboy laughed, joked and told tall tales. By the time he had finished, the temperature outside had fallen to near zero. Doc thought maybe his patient might want to bed down for the night; instead he saddled up and rode 45 miles to a ranch where he had promised to help out with the roundup.*

Learning has come into the world not merely to clear men's eyes and give them mastery over nature and human circumstances, but also to keep them young, never staled, always new like the stars and the hills and the sea and the vagrant winds, which make nothing of times or occasions but live always in serene freedom from any touch of decay, the courses of their being some high law which we cannot disturb.—Woodrow Wilson.

Nobel Prize Winners In Medicine and Physiology

Niels Ryberg Finsen 1903

In recognition of his contribution to the treatment of diseases, especially lupus vulgaris, with concentrated light rays, whereby he has opened a new avenue to medical science.

"Thanks to the work of Downes and Blunt, of Duclaux, Arloing, Roux, etc., it is at present (1897) well established that light possesses an energetic bactericidal power. Thus everything argues, at least theoretically, in favor of the use of light in the treatment of superficial cutaneous diseases caused by bacterial infection, and yet this therapeutic procedure has remained unused to this day.

"Consequently I have thought it my duty to reundertake the study of this important question from top to bottom.

"As light only exerts its bactericidal effects very slowly, it is necessary to concentrate it by means of mirrors or lenses, at the same time excluding the heat rays of the spectrum, because when concentrated they cause burning of tissues."

Finsen then designed and constructed an apparatus that would concentrate light and at the same time reduce or eliminate heat, the main feature of which was a hollow planoconvex lens containing an ammoniacal solution of copper sulfate.

"I have employed the method of treatment by concentrated chemical rays in different infectious skin diseases, but above all in lupus vulgaris, an affection which presents particularly favorable conditions for putting this therapeutic procedure to work. It is known that lupus vulgaris is caused by the tubercle bacillus, that it is a local and quite superficial malady. On the other hand it is well established that light is capable of killing the tubercle bacillus.

"When a plaque of lupus has been subjected for a long enough time to the action of concentrated chemical rays, its margins, previously elevated, become smooth, the redness progressively diminishes, the skin regains its normal color, and ulcerations, when they exist, are cicatrized."*

His Nganga* Failed

Raymond†, a Makorekore aged twenty years, admitted with pains in his abdomen and joints. He consulted a nganga in November 1959, who said he was bewitched by poison which had been added to his meat. The nganga treated him by applying his mouth to various parts of Raymond's body to 'suck' out the evil. He felt a little better after this. But as the pains returned, in June 1960, he consulted another nganga. This doctor also said that he was being harmed by a witch and told him that she was the wife of his sister's brother-in-law. Raymond could think of no reason for her enmity. The nganga made incisions over the patient's chest and back. He improved only slightly after this treatment.‡

*Nganga—Southern Rhodesian witch doctor.

†Raymond was admitted to a Southern Rhodesian hospital after his nganga failed to cure him.

‡Michael Gelfand: Witch Doctor, 1965.

Early Diabetes Mellitus

E. B. COHEN, M.D.*
Minneapolis, Minnesota

WE NEED A guide to the early phases of diabetes mellitus, primarily because there are advantages in early diagnosis. Detection programs are based on this assumption. Discovery of diabetes before its "clinical" or "symptomatic" or "overt" phase might be especially advantageous. Herein lies our best hope of learning to prevent symptomatic diabetes mellitus and of assessing the benefits of therapy during the "pre-diabetic" period, prophylactic use of diet, oral hypoglycemia agents, etc.

Classification

There is a confusing variety of terms for the earliest phases of diabetes mellitus. One arbitrary classification is as follows:[1]

Phase 1:

"Pre-diabetes". In this group the pre-diabetic state starts at birth and lasts up to phase two. Pre-diabetes might be defined to include all diabetes suspects.

Phase 2:

"Sub-clinical diabetes" includes patients who occasionally can be shown on glucose tolerance tests to have diabetes, usually under stress (such as pregnancy). During sub-clinical diabetes, the stress which brings out the weakness may be a cortisone glucose tolerance test (while the patient still has a normal conventional glucose tolerance test).

Phase 3:

"Latent (asymptomatic) diabetes" is the period during which oral or intravenous glucose tolerance tests are abnormal. The patient may have a normal fasting blood sugar and no symptoms. This is sometimes called "chemical diabetes."

Phase 4:

"Clinical", "Symptomatic" or "Overt" diabetes. The 2,400,000 known diabetics in this country have reached phase 4, and have "clinical," "overt," "symptomatic" or "frank" diabetes.

The progression of diabetes is from phase

*From Diabetes Detection and Education Center; 916 East 15th Street.

The author is indebted to Gordon W. Wittich, B.S. in Pharmacy, Chief of Pharmacy, Mt. Sinai Hospital, for his cooperation in compiling the table.

one to two to three to four; this may be rapid or slow. Regression may occur from any of the four phases to the one preceding.

Chemical Signposts

A number of chemical signposts indicates that in the pre-diabetic phase metabolism is already abnormal. Based on these preliminary observations we should eventually have tests to diagnose patients in the pre-diabetic period (phase 1):

Pre-diabetics

1. In a group of pre-diabetics, the mean blood sugars of many glucose tolerance tests were shown to be above the means of the normals.[2]
2. "Immuno-reactive insulin" is higher in pre-diabetics 60 minutes after intravenous injection of glucose than in normals.[3]
3. Insulin-like activity is higher in the fasting state in pre-diabetics than in normals.[4]
4. Pre-diabetics show delayed use of insulin and insulin complexes.[5] This may account for the "hypoglycemic tail" which characterizes their glucose tolerance tests.
5. Free fatty acids are elevated within ten minutes after rapid glucose injection in pre-diabetics.[6] Return of free fatty acid levels to normal is delayed.
6. Synalbumen insulin antagonism is abnormally high in pre-diabetics.

Sub-clinical Diabetics

In contrast, there have been studies of so-called diabetes of pregnancy (phase 2); between pregnancies such patients should show the pre-diabetic picture just described. However, between pregnancies, patients with abnormal glucose tolerance tests during pregnancy may show no difference from normal populations in blood non-esterified-fatty-acid values; in glucose tolerance tests; in free fatty-acid responses, or in quantitative measure of growth hormone. The last observation argues against the school of thought that an elevation of growth hormone levels produces the abnormality in phases one, two or three. Something is going on, though it is not yet possible to test a patient during phase one, and often phase two, and pin a label on him.

At the University of Michigan, there is an on-going study of 169 close relatives of diabetes patients and 100 controls,[7] who started with normal glucose tolerance tests 12 or 15 years ago. All were between 20 and 40 years of age. Cortisone glucose tolerance tests were done. At the beginning of the study only three of 100 controls had abnormal cortisone glucose tolerance tests, judged by two-hour levels of 140 mgm.% glucose or above. Of 169 relatives of diabetic patients, 53 (28%) initially had abnormal cortisone glucose tolerance tests (nine times as many as in the control group). After a 12-year followup of the 53 relatives of diabetic patients with positive cortisone glucose tolerance tests, 26% already were frank diabetics. The other 116, who had negative cortisone glucose tolerance tests initially, produced only five new diabetics (4%). Cortisone glucose tolerance tests apparently have some predictive value in a survey of close relatives of patients with diabetes mellitus.

Clinical Signs

At this point it seems impractical to test large groups of the population (even relatives of diabetes patients) with studies of free fatty acids, insulin-like activity, immuno-reactive insulin, cortisone glucose tolerance tests or growth hormone assays. We now have to suspect the earliest phases of diabetes on clinical grounds. This is a "statistical chance" sort of thing. Any clue picked up adds to the "statistical chance" that a patient has diabetes mellitus now, or will have in the future. It follows that the more alert physicians are to clinical clues of early diabetes, the better the chance of diagnosing pre-diabetes, sub-clinical diabetes and latent diabetes.

Genetic History

A knowledge of genetics helps. Family history alerts physicians to the possibility of early diabetes in a patient. The suspicion may reach 100% certainty (of "pre-diabetes") in the offspring of two diabetic parents, or the identical twin of a diabetic.

Dr. Schumacher points out that a random fasting blood sugar (true) above 90 is strongly suspicious.[8] The suspicion should not be shelved just because glucose tolerance is normal or fluctuates. This test (or the two-hour

post-prandial blood sugar) may be up one week and down the next. A year or two later the diagnosis of diabetes mellitus often becomes obvious.

Reactive hypoglycemia may mean mild diabetes. The "hypoglycemic tail" on a glucose tolerance test may be the first abnormality to be demonstrated.

Glycosuria of stress (as in pregnancy diabetes) should alert the physician. On the other hand, he should not be misled by normal lactosuria of late pregnancy. Postoperative glycosuria must not be dismissed as a stress phenomenon without investigation. Neither should it be explained away on the basis of IV glucose, which often is given during or after surgery. At average rates of administration, IV glucose (5%) should not produce glycosuria, if the renal threshold is normal.

Rapid Shifts in Refraction

The ophthalmologist may pick up a prediabetic patient. Rapid shifts in refraction often result from changes in blood glucose level. Any patient who needs to change his glasses every month should be checked for diabetes mellitus. Xanthomata* of the eyelids (or elsewhere) and hyperlipemia retinalis are associated with high blood fats often seen in early diabetes. Extra-ocular muscle palsies accompany diabetes; if such is the case, prognosis is good and muscle paralysis may disappear after one or two months of good therapy. If it does not, a neurologist and/or neurosurgeon should be consulted. Other cranial nerves are occasionally involved in an early diabetic neuritis. Deterioration of the eighth nerve, for example, may be the first sign of diabetes. The hearing deficit may be a "fatigue deafness;" with repeated testing, performance of the patient seems to get worse.

Visceral Neuropathy

Visceral neuritis occasionally is the first symptom of diabetes. Early impotence, gastrointestinal complaints (including nocturnal diarrhea) and atonic bladder should suggest a glucose tolerance test.

Peripheral Neuropathy

Peripheral neuritis in diabetes mellitus produces symptoms as varied as the functions of the peripheral nerves. Olson and Schumacher[9]

have shown that where conduction time measurements have been done, diabetic neuritis may be accompanied by slowed nerve conduction. One useful by-product is that diabetic neuritis may affect plans for surgical approach to such things as disc disease accompanied by neuropathy.

Dermatitis

Dermatologists often contribute to early discovery of diabetes. The skin lesion need not be as typical as "necrobiosis lipoidica." Patients with psoriasis are often diabetics. The skin lesion called dermatitis gangrenosa (with blisters or bullae) may be an early sign of diabetes mellitus. Xanthomata have been mentioned. Depuytren's contracture is associated, in a high proportion of cases, with diabetes.

Heavy Babies

The obstetrician can help. Everyone knows that a history of heavy babies makes the mother suspect. Early diabetes should also be suspected in cases of intra-uterine death, hydramnios, toxemia, kidney complications, vascular accidents and congenital anomalies.

Premature Vascular Disease

Premature vascular degeneration may be a clinical clue. Early coronary disease, for example, should make one suspect diabetes mellitus. The rule often used is that a coronary in a patient under 50 (especially if female) suggests diabetes. Similarly, early peripheral vascular disease (especially small-vessel disease as opposed to the occlusion of a large vessel) may be an early clue. Just as discovery of diabetic neuritis might slow up the surgical approach to co-existing surgically correctable causes (such as disc), so discovery of diabetic peripheral vascular disease should temper the decision of the vascular surgeon.

Other Associated Diseases

A number of metabolic and endocrine diseases are known to be associated with diabetes. In some cases this seems to be merely a statistical thing; in others, the hormonal abnormality causes diabetes, or brings out a latent genetic tendency. Included in this list should be gout, acromegaly, hyperthyroidism (Graves[1] disease), hypercorticosteroidism (Cushing's syndrome and hyperaldosteronism), pheochromocytoma and hyperglucagonism.

Not to be ignored is the increasingly long list of hyperglycemic drugs and hormones currently prescribed. Patients discovered to have hyperglycemia after administration of these compounds should be considered pre-diabetics who have been "unmasked" by a relatively minor stress (Table 1).

If sufficient attention were paid to these clinical clues by all physicians, the result would be a most effective diabetes detection program. The diagnosis of early diabetes mellitus is a "statistical chance" sort of thing. Any clue picked up adds to the "statistical chance" that a given patient will prove to have diabetes now, or in the future. The search is worth the trouble. We have reached the point where treatment of early diabetes may postpone or prevent "symptomatic" or "overt" diabetes.

Autohemic Therapy

For many years one L. D. Rogers was the head and chief owner of the National Medical University of Chicago. The school was a low-grade institution, virtually a diploma mill. Rogers is a promoter of medical schemes and fancies. Like many other cultist leaders he is constantly founding societies of which he is the chief panjandrum. . . Finally, he got the notion called "autohemic therapy." "It consists," he says, "in giving the patient a solution made by attenuating, hemolizing, incubating and potentizing a few drops of his or her own blood, and administering it according to a refined technic developed by the author." . . He wrote a book called "Autohemic Therapy" and organized the Autohemic Practitioners. Newspaper publicity in the form of full-page advertisements and clever press agentry fetch the come-ons for the course. The appeal is made cleverly to the antimedical cultists of all varieties by the slogan "without use of bugs or drugs." A clever and shrewd old fakir is L. D. Rogers!*

Early Detection and Control of Diabetes*

GLEN W. McDONALD, M.D.†
Arlington, Virginia

THE FIRST STEP in fighting diabetes is finding the diabetic. According to the National Health Survey's most recent estimates, there are 2.8 million diagnosed and 1.6 million undiagnosed diabetics. Current studies indicate that these figures are conservative.

Screening

The process by which we find and identify suspected diabetics is called screening. Screening is the presumptive identification of unrecognized disease by a variety of rapidly applied testing procedures. In order to detect diabetes in its earliest stages, screening programs must be expanded and become more selective.

The superiority of blood testing over urine testing is beyond question. The blood test is not only more sensitive, but also far more specific. Using blood tests makes it possible to identify more diabetics while sending fewer false positives to already busy private physicians. Furthermore, improved laboratory analysis of blood glucose on the Auto Analyzer has increased the efficiency of our screening techniques: now 40 to 60 specimens per hour can be analyzed.

High Yield Groups

Why do we screen? Efficient epidemiological programs produce maximum results with a minimum investment of time, money, and effort. Furthermore, screening enables the practicing physician to best utilize his skills. He can concentrate on those most likely to need his professional services—those who are over forty, overweight, relatives of diabetics, and mothers who have given birth to babies weighing more than nine pounds.

These high-yield groups have, on experience, produced the largest proportion of diabetics.

*Presented at the dedication of Diabetes Detection & Education Center, Minneapolis, Minnesota, November 10, 1967.

†Chief of the Diabetes and Arthritis Control Program, National Center for Chronic Disease Control, Bureau of Disease Prevention and Environmental Control, Public Health Service, Department of Health, Education, and Welfare, Arlington, Virginia.

The most effective screening program must be concerned not only with looking for diabetes among these particular population groups, but also must see that positive screenees are brought to diagnosis (and treatment when necessary) and that physicians cooperate in reporting diagnosis results.

Approximately 800,000 Americans were blood-tested for diabetes last year.* Out of this number, only 7,700 new diabetics were discovered. This is a very disappointing figure when we consider that there are an estimated 1.6 million "hidden" diabetics. The figure is also disappointing when we consider the number of diabetics that *can* be discovered *if* we concentrate our efforts in those areas where diabetics are found in greatest numbers. There is not a screening program in the U.S. that could not double its yield of new cases with very little additional effort or expense by more thorough and sensitive screening techniques.

Today's problem is not just to find and treat diabetes, but to find and treat it as early as possible. Although we have no cure for diabetes, it can be easily controlled with diet, medication, and exercise. The disease can be better controlled if it is discovered early when the manifestations are minor and less injurious to health.

The best screening programs are those that are organized as joint efforts of local health departments, medical societies, and diabetes associations. Each of these groups offers specialized skills that the others cannot provide. A combination of these separate talents and skills should produce adequate leadership for any local epidemiological experiment.

Federal Employee Group

Our experience with the Federal Employee Screening Program has shown that periodic retesting of those who have had prior positive tests, but have not been diagnosed diabetic, will identify many new cases. Since July 1960, more than 50,000 federal employees have been screened in nine cities across the nation. Screenees are instructed to eat their usual breakfast and fast for two hours after reporting for work. At that time each person is given a 75 gm. carbohydrate cola drink (glucola). Venous blood specimens are drawn between one hour and 45 minutes and two hours and 15 minutes after the carbohydrate is taken.

For this program the screening level for positives is relatively low: 130 mg. per 100 ml. Tests are made on plasma which is easier to analyze than whole blood but gives higher readings. Direct referral is made to private physicians for diagnosis when the screening plasma value is 300 or more. When the screening level is between 130 and 299, glucose tolerance tests are administered by the health unit physicians.

In 1964, 10.9 percent tested positive and 2.1 percent were confirmed as new diabetics. This is the highest figure we have obtained since the study began. In 1965, 9.5 percent tested positive and 1.6 percent were confirmed new diabetics.

Suspects

Unfortunately, there are no adequate estimates of the number of persons in the U.S. who can be considered diabetes "suspects." Such estimates are not easy to obtain, and agreement on definitions and criteria is difficult to reach. But available data indicate that the number of diabetes suspects may be very large. Because we anticipate an exceptionally high yield from this group, their discovery should be of prime importance to any screening program.

Suspects are of two types: unsuccessful referrals and borderline cases. Unsuccessful referrals are those positive screenees who either failed to report to the doctor for diagnosis or were incorrectly diagnosed. Borderline cases have registered blood glucose levels just below the referral line. With a lower screening level, the latter group would have been referred to a physician for diagnosis.

The importance of suspects can be supported by some of our experiences with the Federal Employee Screening Program. In a special study, those who did not volunteer for retest were invited to have a glucose tolerance test. In a two-year period (1961-62), 18,690 federal employees were screened in the Washington area, yielding 1,922 positives and 259 new cases; 3,151 of those who originally tested negative volunteered for retesting. The yield from this group was 14.0 per thousand (almost

*As reported voluntarily to the United States Public Health Service: Some diabetes screening programs do not report.

as high as the total yield for the original group of screenees). Of the positive screenees who had not been diagnosed diabetic, 843 received either an additional screening test or a glucose tolerance test. In this group, 128 additional cases of diabetes were identified. Thus almost one in four of the persons with initial positive results was identified by a private physician as diabetic. Further testing of this suspect group gives us an unusual opportunity to test the preventive measures that we presently know about—particularly weight reduction and control—and to apply new research findings.

Elevated Blood Glucose with Negative Retest

Our considerable experience with diabetes screening programs has taught us that testing should be continuously provided for persons who have exhibited elevated blood glucose levels, even if the retest results have been negative and they have, therefore, not been referred to physicians (or were referred but received no diagnosis). The yield of new cases of diabetes among this group is exceedingly high even when a retest is done within two years of initial testing. We must not assume that a large proportion of those with positive screening results but no physician's diagnosis will voluntarily seek another test.

People Over Forty

In mass screening efforts, particular attention must be given to testing people over 40, as this is where we have found the largest proportion of new cases. Little can be accomplished by testing those under age 25. Even less significant results can be expected from testing those under 15 years of age (among children under 15, only one in 2,500 will have diabetes).

What can be done, then, to solve these multiple problems of finding the "hidden" diabetic? First of all, the practicing physician must cooperate fully with the screening program in the planning and evaluation stages. He must be the chief agent for diagnosis and followup (and continuing followup). His findings should be sent to the screening center to allow for the continual evaluation of the effectiveness of the screening program.

Disposition

At the screening program, screenees should be warned that the screening test is not a diagnosis, and that further tests and referral to a physician may be necessary. Positive screenees should be informed of their test results and scheduled for a retest appointment. Screenees should also be informed of retest results. Those who retest positive should be referred to a physician. Each referral letter to the physician should be accompanied by a form to be filled out and returned when diagnostic studies are completed.

The private practicing physician is the chief man on the diabetes control team. He sees those patients in his office who may not be reached by mass screening programs—especially those who are over forty, overweight, related to a diabetic, or women who have given birth to babies weighing more than nine pounds. The practicing physician must be on the lookout for the classical symptoms of diabetes: those who have spilled a little sugar during pregnancy or have unexplained neurological manifestations, frequent changes in visual acuity, slow wound healing, etc. Persons evidencing any of these characteristics should be blood-tested for diabetes once a year.

The physician must be prepared to inform all diabetes suspects of the nature and symptoms of the disease. He must instruct, or arrange instruction for the patient in diet, urine testing, insulin injection and measurement, syringe sterilization and other equipment maintenance, general body hygiene, and dental and foot care. The patient should also be warned of probable complications. The physician must join in the search for new methods and techniques of patient education, including programmed instruction, team-teaching, audio-visual aids, etc.

The physician should be acquainted with all available patient information and teaching resources (local diabetes associations, local medical societies, etc.). We cannot assume that because a patient has been instructed in the maintenance and care of his disease he is fully informed. Repetitive teaching is a must.

The private physician, then, assumes the responsibility of testing, diagnosing, prescribing,

counseling, and followup. He can be an even bigger help if he is on the lookout for signs of diabetes and tests accordingly in his own office. He must be on the alert for the high-risk groups. Then, and only then, will he be able to discover diabetes in its earliest stages when damage is slight and the chances for progression and complications are reduced. Only if every physician, in his office and in cooperation with health agencies, local diabetes associations, and medical societies, actively lends himself to diabetes screening and follow-up activities, will we be able to find the 1.6 million undiagnosed cases at large today.

Abdominal Migraine Syndrome

Various writers have classified as a syndrome the symptoms of abdominal pain, nausea, vomiting, and sometimes diarrhea that are frequently a conspicous part of the clinical picture of migraine (Brams, Blumenthal). The abdominal migraine syndrome is seen primarily in children or in adults who have had migraine for many years. Typical is a history of colic as a baby and a family history of headache or biliousness or both. Not infrequently the abdominal symptoms continue during childhood without attacks of headache, or may alternate in their occurrence with attacks of cephalalgia, or may continue after the headache has ceased. Parenteral administration of ergotamine usually causes prompt subsidence of symptoms. Desensitization with intravenous histamine affords more prolonged relief.

Shakespeare: on the Effects of Poison

"There is so hot a summer in my bosom,
That all my bowels crumble up to dust:
I am a scribbled form, drawn with a pen
Upon a parchment, and against this fire
Do I shrink up."

"How fares your majesty?"

"Poison'd, ill fare; dead, forsook, cast off:
And none of you will bid the winter come
To thrust his icy fingers in my maw,
Nor let my kingdom's rivers take their course
Through my burn'd bosom, nor entreat the north
To make his bleak winds kiss my parched lips
And comfort me with cold."

"O that there were some virtue in my tears
That might relieve you!"

"The salt in them is hot.
Within me is a hell; and there the poison
Is as a fiend confin'd to tyrannize
On unreprievable condemned blood.
The tackle of my heart is crack'd and burn'd,
And all the shrouds wherewith my life should sail
Are turned to one thread, one little hair;
My heart hath one poor string to stay it by."*

Diabetic Angiopathy and Sulfonylurea Therapy*

MARIOS C. BALODIMOS, M.D.†
ALEXANDER MARBLE, M.D.†
Boston, Massachusetts

THE INTRODUCTION OF INSULIN in the therapy of diabetes in 1922 has saved the lives of millions of persons and has increased considerably their life expectancy. The prolongation of life by insulin has resulted, however, in an increase in the frequency and extent of atherosclerosis and microangiopathy among patients who live for long periods with their disease. This increase has led to studies to elucidate the presumed deficiencies of insulin therapy or even to reveal its causative role for these complications. Neither has been accurately clarified. Very few clinicians blame exogenous insulin for deleterious effects, except for the hazard of hypoglycemia and its consequences. After 45 years the basic safety of insulin use remains undisputed.

The sulfonylurea compounds, introduced in 1955, have made treatment more convenient for many older patients; the number of those responsive to such therapy has been variously estimated as 25 to 40% of all diabetics. Furthermore, the safety record of these compounds has been satisfactory.

Morbidity and Mortality

It is now possible, after more than a decade of use of oral hypoglycemic agents, to appraise their effectiveness in preventing or postponing atherosclerosis and the specific microangiopathy of diabetes which are responsible for most of the morbidity and mortality of the disease. Sulfonylureas have been considered to possess not simply hypoglycemic, but also "antidiabetic" properties, because they promote the release of endogenous insulin. However, their record in protecting from complications has to

be compared with that of insulin therapy, in order to determine whether oral sulfonylurea therapy is superior to insulin, and also whether it is equal to or at least not inferior to insulin in postponing vascular complications.

Sulfonylureas have been used at the Joslin Clinic on several thousand diabetic patients.[1-4] In a series of clinical studies[5-8] we have attempted to answer the above questions.

Vascular Complications

Of a total of 125 patients who had taken tolbutamide for eight to 10 years continuously 101 were examined for the presence of diabetic angiopathy and these findings were compared "blindly" to those in suitable controls, i.e., 87 patients with "mild" diabetes who had never received oral sulfonylurea therapy and who had been treated either with small doses of insulin or with dietary restriction alone. It was found that angina pectoris or myocardial infarction, cerebral vascular accidents and peripheral vascular disease occurred with equal frequency in the tolbutamide-treated patients and in the controls[6] (Figure 1).

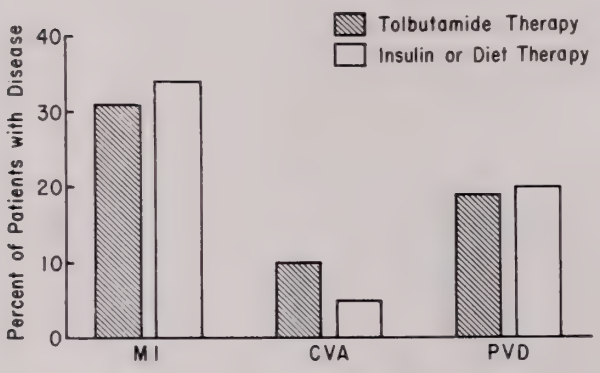

Fig. 1—Cardiovascular disease after eight to 10 years of tolbutamide therapy. MI = Angina or myocardial infarctions; CVA = Cerebral vascular accidents; and PVD = Peripheral vascular disease.

Diabetic Nephropathy

The clinical demonstration of diabetic nephropathy is difficult and unreliable. Indirect indices of renal function may be used. In this study[6] significant proteinuria was rare in both groups and blood urea nitrogen levels were no higher in the sulfonylurea group than in the controls.

Diabetic Retinopathy

Diabetic retinopathy, on the other hand, can be easily demonstrated by careful ophthalmoscopic examination, following dilatation of the pupils. We recorded and documented these changes by fundus photography both in patients treated with sulfonylureas and in controls treated with small doses of insulin or with diet alone. Retinopathy was found in 40% of the total of 152 patients. The relative frequency of retinopathy in those treated with sulfonylureas and in the controls was not significantly different.[8] Retinopathy in sulfonylurea-treated patients was found also by others[9,10] with similar or lower frequency compared to insulin-treated patients.

Although the frequency of retinopathy did not seem to be influenced by the form of antidiabetic therapy it was significantly dependent on the lack of "chemical" control of the metabolic abnormality. Irrespective of type of antidiabetic therapy, those who had maintained good control of diabetes (as determined by another observer independently and in a "blind" fashion) had a significantly lower frequency of diabetic retinopathy than those with only fair or poor control[8] (Figure 2). Reports of the majority of investigators who had studied the frequency of angiopathy in relation to the degree of control of diabetes are in agreement with the above findings: namely, that angiopathy is found more frequently among patients who have had an unsatisfactory control of diabetes over the years.[11]

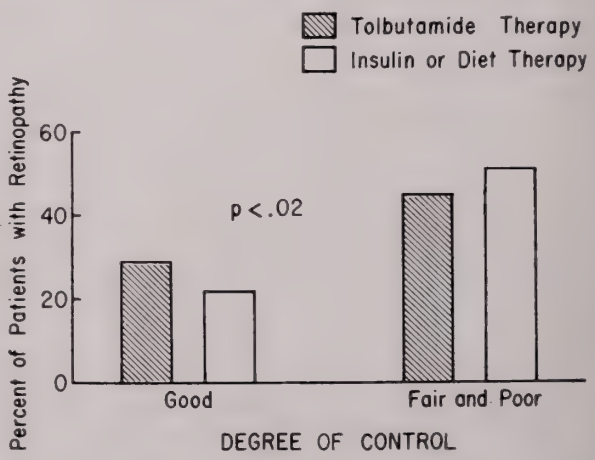

Fig. 2—Diabetic retinopathy in patients under various forms of therapy and different degrees of diabetic control.

Death and Pathologic Findings

The causes of death, as reported on death certificates, of all Joslin Clinic patients treated with sulfonylurea compounds for variable periods were compared with the causes of death of all patients of the Joslin Clinic, with onset of diabetes after 40 years of age, who died between 1956 and 1964[5] (Table 1). A remarkable similarity of causes of death is evident from this table between sulfonylurea-treated patients and total deaths at the Joslin Clinic, indicating again that there was no obvious shift in the morbidity on account of sulfonylurea therapy.

In a later study we compared, in a "blind", unbiased fashion, the autopsy findings of 55 patients who had received sulfonylurea therapy for an average of 46 months with those of suitable controls who had been treated with insulin or diet alone.[7] Pathologic evidence of myocardial infarction, diabetic nephropathy, diabetic retinopathy and cerebral vascular accidents was found with equal frequency in sulfonylurea-treated and control patients (Figure 3). The frequency of peripheral vascular disease as evidenced by gangrene and/or amputation of a lower extremity was actually greater in insulin-treated patients ($P < .05$). This was attributed to the customary use of insulin in diabetic patients with severe infection and gangrene.

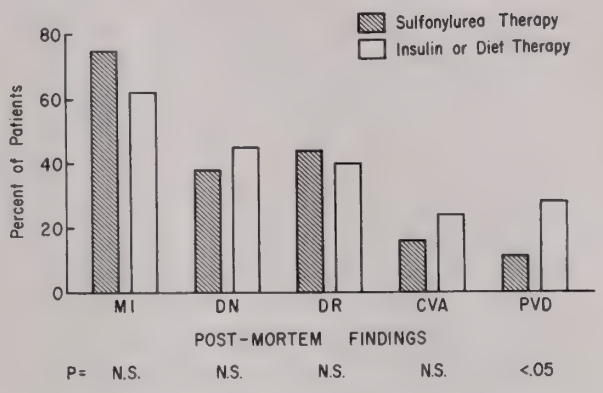

Fig. 3—Post-mortem findings after long-term sulfonylurea therapy. MI = myocardial infarcts; DN = diabetic nephropathy; DR = diabetic retinopathy; CVA = cerebral vascular accidents; and PVD = peripheral vascular disease.

Conclusions

The results of the studies referred to above[5-8] are reassuring. They include studies on large numbers of patients, both living and dead, treated for fairly long periods of time with sulfonylurea compounds, and compared to suitable controls. These studies have failed to show a higher frequency of cardiovascular, cerebral or peripheral vascular disease after oral therapy. Similarly, no differences were observed in the major clinical manifestations of diabetic microangiopathy, i.e., retinopathy and nephropathy.

On the other hand, no superiority of sulfonylurea over insulin therapy in the prevention of diabetic angiopathy was evident. Hence the results of this study suggest that one should not expect to achieve results superior to those obtained by insulin therapy, as was hoped initially after the introduction of oral agents. The factors responsible for the development of microangiopathy and for the accelerated

TABLE 1.
Causes of Death in Patients with Onset of Diabetes after Age 40*

Cause of death	All known deaths of diabetic patients. 1/1/1956-2/19/1964 No.	Percent	All patients who received sulfonylureas No.	Percent
Cardiovascular disease (incl. gangrene)	3146	(58%)	328	(60%)
Cerebral vascular disease	751	(14%)	77	(14%)
Renal disease	244	(5%)	28	(5%)
Total vascular deaths	4141	(77%)	433	(79%)
Cancer	631	(12%)	64	(12%)

*Experience of the Joslin Clinic. Data tabulated with the collaboration of the Statistical Bureau of the Metropolitan Life Insurance Company.

morbidity and mortality from atherosclerosis in diabetes mellitus, including severity of the underlying defect, etc., still remain elusive. Careful "chemical" control of the metabolic abnormality, by whatever means, gives the best results and is at present the best known guaranty for postponing and minimizing the vascular complications of diabetes.

It takes a heap o'livin' in a house t'make it "home,"
A heap o' sun an' shadder; an' yer sometimes hev t' roam
Afore yer reely 'preciate the things ye lef' behin'
An' hunger for 'em somehow, with 'em allus on yer mind.
It don't make any differunce how rich yer git ter be,
How much yer chairs and tables cost, how great yer luxury.
It ain't "home" to yer, tho' it be the palast of a king,
Until, somehow, yer soul is sort o' wrapt 'round everything!—*Anon.*

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Whipple's Disease*

Early Diagnosis

RICHARD BORNSTEIN, M.D.†
ATHANASIOS THEOLOGIDES, M.D., Ph.D.‡
B. J. KENNEDY, M.D.§
Minneapolis, Minnesota

WHIPPLE FIRST DESCRIBED the disease which bears his name in 1907.[1] The original report has been referred to as a "classic of clarity, objectivity and completeness."[2] All the outstanding features of this disease were recorded, including the presence of rod-shaped structures in a lymph node. However, the syndrome of migratory arthritis, diarrhea, abdominal cramps, progressive weight loss, cutaneous hyperpigmentation, and lymphadenopathy represents the more advanced and terminal stage of the disease.

Since Whipple's disease has been shown recently to be potentially curable with appropriate antibiotic therapy, it is advantageous to establish the diagnosis early. This is exemplified by a patient in whom the initial clinical diagnosis of lymphoma had previously been made. In failing to respond to cyclophosphamide therapy a re-evaluation of the illness established the diagnosis of Whipple's disease.

Case Report

History

This 59-year-old white male farmer was readmitted to the University of Minnesota Hospitals in August, 1967, complaining of weight loss, abdominal cramps, anorexia and diarrhea. The past medical history revealed 20 years of intermittent migratory arthritis involving predominantly the hands, wrists, and ankles, and two years of increased fatigue and weakness. In the fall of 1966 he noted intermittent constipation, occasional fever and night sweats, and a "lump" in the abdomen. Because of these symptoms he consulted his physician in April, 1967.

Examination

Physical examination revealed a left upper quadrant abdominal mass and axillary and inguinal lymphadenopathy. An anemia was treated with transfusions. An exploratory laparotomy revealed diffuse

Fig. 1—Roentgenogram of upper gastrointestinal tract including part of small bowel, showing coarsening and thickening of the mucosal folds and dilation of the small intestine.

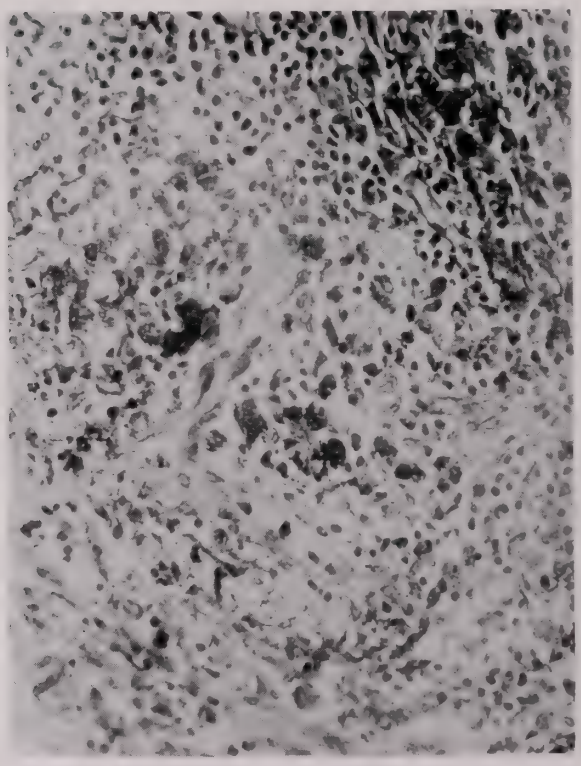

Fig. 2—Lymph node showing PAS positive particles (PAS stain × 250).

lymphadenopathy, and the histologic appearance suggested Hodgkin's disease. This material along with biopsies of the axillary and inguinal nodes was subsequently interpreted as probably benign adenitis.

He was referred to the University of Minnesota Medical Center in May, 1967, for further evaluation. Physical examination showed a pale, cachectic, chronically ill man. Small, firm lymph nodes were palpable in the cervical, axillary, and inguinal regions, and an ill-defined upper-quadrant abdominal mass was detected. Ulnar deviation of the wrists was noted.

Laboratory Studies

Laboratory studies revealed a hemoglobin of 11.4 g/100 ml., a sedimentation rate of 105 mm. at one hour, occult blood in the stool, serum albumin of 2.6 g/100 ml., and serum gamma globulin of 3.6 g/100 ml. with a diffuse peak in the electrophoretic pattern. An upper gastrointestinal radiographic examination was normal. A peroral small intestinal biopsy yielded insufficient material for study. The lymph node biopsies were interpreted again as non-specific inflammatory change. On clinical grounds it was decided to treat the disease as a lymphoma; a course of intravenous cyclophosphamide was given followed by maintenance oral administration for two months.

In August, 1967, the patient described watery diarrhea, abdominal cramps, anorexia, and further weight loss. An additional physical finding of hyperpigmentation of the exposed areas of the skin was noticed for the first time.

The hemoglobin was 8.6 g/100 ml., white blood cell count 4,800 mm^3, platelet count 403,000 mm^3, and sedimentation rate 112 mm. in one hour. Occult blood persisted in the stool. The fecal fat was increased at 18 g/day, and the serum carotene and vitamin A levels were decreased. An upper gastrointestinal x-ray series with small-bowel follow-through revealed coarsening and thickening of the mucosal folds and dilation of the small intestine, particularly of the distal duodenum and jejunum (Figure 1). Peristalsis also appeared sluggish, but passage of the contrast media was normal through the small bowel. A barium enema revealed occasional small diverticula. An axillary lymph node biopsy and a subsequent small intestinal mucosal biopsy were diagnostic of Whipple's disease (Figures 2-5).

The patient was given a 14-day course of procaine penicillin 600,000 units and streptomycin 0.5 g. intramuscularly twice a day. Marked improvement occurred by the end of the first week of treatment, consisting of increased appetite, weight gain, and a return of bowel function to normal. The patient was then begun on tetracycline, 250 mg., four times a day, to be continued for a period of ten to twelve months.

Discussion

Whipple's disease typically involves middle-aged white males and is clinically characterized by arthritis, hyperpigmentation of the skin, abdominal cramps, diarrhea, weight loss, fever,

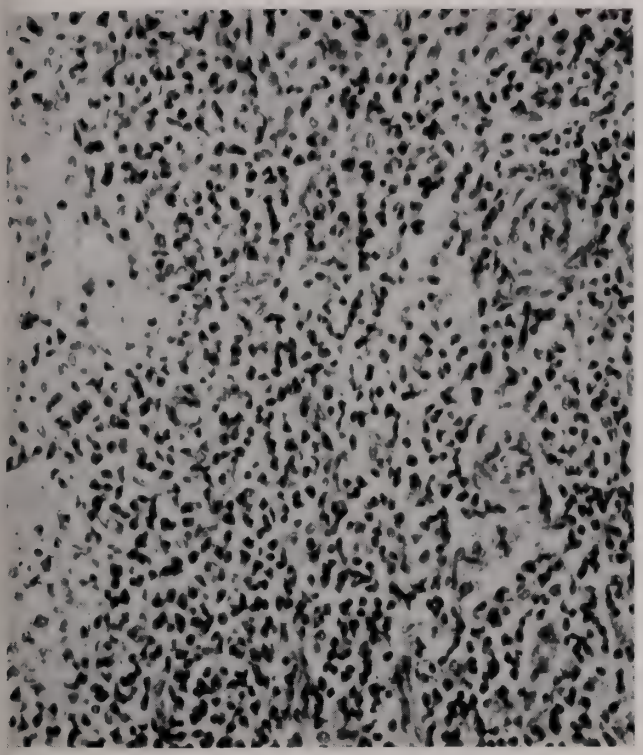

Fig. 3—Lymph node showing histiocytic infiltration (Hematoxylin and Eosin × 250).

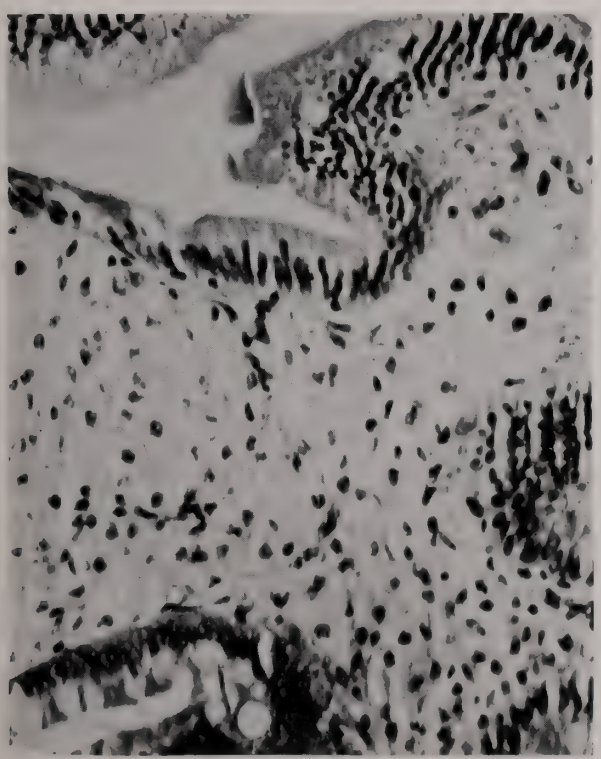

Fig. 4—Small bowel showing shortened and broadened villus and histiocytic infiltration (Hematoxylin and Eosin × 250).

and lymphadenopathy. Laboratory findings include steatorrhea and malabsorption, anemia, elevated sedimentation rate, and occult blood in the stool. Roentgenograms of the small intestine are characterized by coarsening of the mucosal folds with or without segmentation and flocculation.[3] Within recent years these features have been amplified, but little emphasis has been placed on the early diagnosis prior to the development of the full-blown syndrome. A patient is reported in whom the opportunities for early diagnosis were present but not utilized.

Intermittent Arthritis

This patient had intermittent arthritis over a 20-year period which probably represented the initial manifestation of this disease process. In Whipple's patient the migratory arthritis antedated other symptoms by more than five years. Kelly and Weisiger's review of 95 cases of Whipple's disease revealed arthropathy in at least two thirds of the cases.[4] When present, it usually precedes the other symptoms by several years. The joint symptoms characteristically consist of episodes of intermittent migratory arthralgia or arthritis, lasting several hours to several days, but then resolving

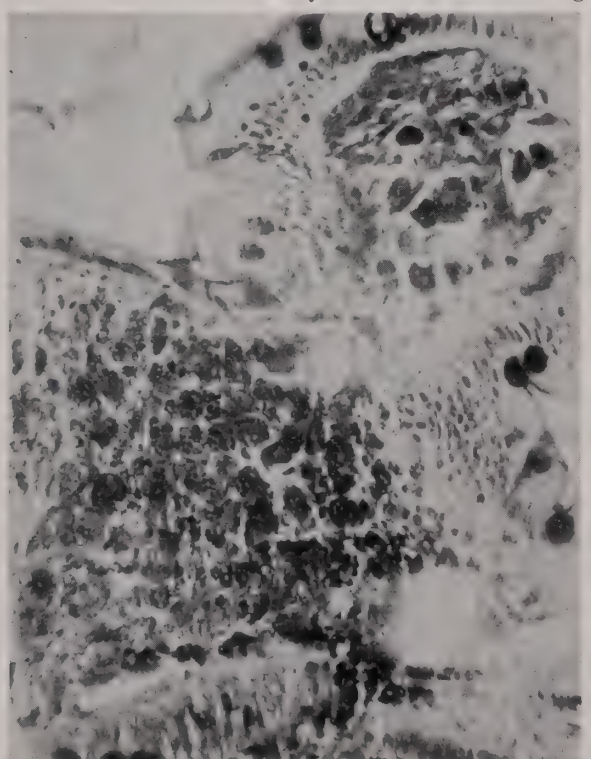

Fig. 5—Small bowel showing extensive PAS positive material (PAS stain × 250).

completely, leaving no residue. Long periods of remission from the arthritis during the early stage of the disease have been observed, and in some cases remission of the arthritis occurred with the onset of the abdominal symptoms.[5] Peripheral joints were most commonly involved and frequently this was bilateral. Spondylitis was found in almost 20% of the cases with Whipple's disease, all of whom had peripheral arthritis as well.

Periodic Acid Schiff's Positive Staining

Thus arthritis is often the earliest manifestation of Whipple's disease. The occurrence of nonspecific arthritis, especially associated with any of the other features of this syndrome should alert one to the diagnosis of Whipple's disease. Since Sieracki has reported periodic acid Schiff's (PAS)-positive inclusion bodies of the synovial lining cells,[6] biopsy of the joint with periodic acid Schiff's staining may prove to be a simple technique for establishing an early diagnosis.

Constipation

Profuse watery diarrhea is considered the cardinal manifestation of Whipple's disease. Although not infrequently the initial symptom, it is more commonly a late manifestation. Once diarrhea begins, the course is often one of progressive deterioration resulting in death. Constipation has not been emphasized; however, a review in 1950 reported over 25% of the patients to have constipation, either preceding the diarrhea or alternating with it.[7] There were also two patients with constipation who failed to develop diarrhea at any time during the course of the disease. Our patient initially had constipation, and only later developed diarrhea. Thus the absence of diarrhea does not exclude the diagnosis of Whipple's disease, and the presence of constipation may be the first or only gastrointestinal clue.

Skin Hyperpigmentation

Hyperpigmentation of the skin has not been adequately emphasized as a manifestation of Whipple's disease, although it was present in one half to two thirds of the reported cases.[8] Recent textbooks on dermatology do not mention Whipple's disease in the differential diagnosis of hyperpigmentation,[9,10] which is characterized by its marked variation in distribution and intensity. One study has commented that there are no reports of pigmentation without the presence of diarrhea.[11] Likewise in our patient, the pigmentation was not recognized until after the onset of the diarrhea. Although not usually reported in the prodromal period, subtle changes in pigmentation may well be present for some time before they are noted, a fact which may serve as an important clue in the early diagnosis of Whipple's disease.

Lymphadenopathy

Lymphadenopathy is found in 50% of the patients.[12] When combined with weight loss, fever, night sweats, and anemia there is a clinical resemblance to lymphoma, as is vividly illustrated in the present report, since the patient was initially treated for lymphoma. When lymphadenopathy is present, these nodes provide a readily available means of establishing the diagnosis. Histologic demonstration of periodic acid Schiff's-positive material is diagnostic and emphasizes the indication for this stain in cases of otherwise nondiagnostic lymph nodes (Figure 2).

Histopathology

While the presence of Whipple's disease may be suspected on clinical grounds, the diagnosis is established by histologic examination of lymph nodes, small intestinal mucosa, or possibly synovial membrane. With routine staining there are seldom characteristic morphological findings in these tissues (Figures 3 and 4). In 1949, Black-Schaffer demonstrated periodic acid Schiff's-positive macrophages within the small bowel mucosa.[13] These macrophages are considered to be the major diagnostic feature of the disease. They can be found in many tissues but are most prominent in the lamina propria of the small intestine (Figure 5). Other features in the small intestine are flattening or clubbing and fusion of the villi and the accumulation of fat-filled spaces in the mucosa;[14] but these features are of variable intensity and may be absent.

The recent demonstration of rod-shaped structures in and around the macrophages in jejunal biopsy specimens renewed interest in this disease.[15,16] Their presence has been confirmed in epoxy-embedded specimens under

light microscopy; they are not seen in routine paraffin sections. They are most abundant between macrophages, but individual bacilliform bodies have been seen within the cytoplasm of the macrophages.[14] With electron microscopy these rod-shaped structures have the typical fine appearance of bacteria.

Identity of Progressive Improvement

Following antibiotic treatment and during a period of remission, there is progressive improvement in the structure of the villi, disappearance of bacteria, and decrease in the number of periodic acid Schiff's-positive macrophages. Electron microscopy then reveals the absence of bacilliform structures.[17]

Thus, peroral small intestinal biopsy provides a specific method for establishing the diagnosis of Whipple's disease. It has proved to be a simple and safe procedure and should be considered in all cases of nonspecific arthropathy or enteropathy.

Bacteriology

Various bacteria have recently been isolated from patients with Whipple's disease and have been incriminated in its pathogenesis. Caroli et al. recovered a corynebacterium from an inguinal node,[18] Kok et al. isolated a corynebacterium and a hemophilus organism from the jejunum,[19] and Kjaerheim et al. demonstrated a hemophilus strain from intestinal mucosa.[20] Most recently, Charache et al. have grown atypical bacteria (bacteria with damaged or absent cell walls) from the blood and lymph nodes of a patient with Whipple's disease.[21] The presence or absence of this organism which proved to be a group D enterococcus correlated with the clinical status of the patient. These organisms could revert to typical bacterial form. It was suggested that "failure to identify this pathogen in the past may readily be explained by its presentation in atypical form."

Attempts to culture atypical forms in our case prior to treatment were unsuccessful; similar negative culture results are the rule in this disease. At this point no specific microorganisms can be incriminated as the etiologic agent in Whipple's disease. This is not to deny the role of these organisms, but only to emphasize the difficulties encountered in their isolation. Nevertheless, the possibility remains that the syndrome can be produced by several different organisms. Furthermore, certain host factors may play a significant role in the pathogenesis of the disease.

Summary

A patient with Whipple's disease provided the opportunity to emphasize the early manifestations of this syndrome. Nonspecific arthropathy may precede other manifestations by several years. Diarrhea is often a late symptom but may be absent entirely, while constipation may be the first or only gastrointestinal symptom. Furthermore, Whipple's disease should be considered in the differential diagnosis of hyperpigmentation of the skin. Lymph node biopsy or peroral small intestinal biopsy, when positive with periodic acid Schiff's stain, establishes the diagnosis in a clinically suspected case. Thus the means for early diagnosis are available for a disease which is potentially curable.

ELECTROCARDIOGRAPHICS

I am a second-year medical resident at the Minneapolis Veterans Administration Hospital. Last year, while reading electrocardiograms as a resident at Hennepin County General Hospital, I became fascinated with the way one could arrange electrocardiograph terms so that they demonstrated their meanings.

The above are some examples which I thought might be fun to publish.

Esophageal Resection*

Gastroesophageal Anastomosis

THEODORE A. PETERSON, M.D.
FRANK E. JOHNSON, M.D.
JOSEPH C. KISER, M.D.
Minneapolis, Minnesota

RESECTION OF THE thoracic esophagus has become a frequent and standard surgical procedure. Following resection of the esophagus, the surgeon is presented with a difficult decision in determining what method of reconstruction would be best for a specific patient. Many methods have been described and are in varying degrees of use at this time. One of the choices for reconstruction is the utilization of the stomach transplanted into the chest.

This presentation concerns a recent review of records of patients who have undergone a specific operation involving the transplantation of the stomach into the chest. This procedure includes resection of the distal and mid-esophagus and anastomosis of the esophagus to the stomach, high within the thoracic cavity. Thus the stomach comes to reside within the thorax.

The patients include those seen in our surgical practice from January 1956 through January 1966, a 10-year period, 36 of whom have undergone this specific surgical procedure. Their records have been reviewed and constitute the substance of this report. All operations were either performed, or were directly supervised, by one of the members of this office.

History

The first successful surgical resection of a carcinoma of the mid-esophagus was accomplished by Dr. F. Torek[1] and was reported in 1913. This patient survived longer than five years and represents an apparent cure. No reconstruction was attempted, and the patient lived with a cervical esophagostomy and a gastrostomy. As recently as 1938, Dr. William Adams and Dr. Dallas Phemister found the reports of 17 such operations in the medical literature[2] and reported one additional case. In 1945, Dr. Richard Sweet of Boston presented a summary of nine cases of resection of the esophagus with reconstruction

*Presented at the Minneapolis Surgical Society Meeting, November 2, 1967, in Minneapolis.

utilizing the thoracic stomach.[3] Since that time, numerous additional reports have appeared in the literature.[4,5]

Technique

The operations performed in these 36 patients were basically similar, being varied only to meet certain individual requirements.

Abdominal Portion

A long midline abdominal incision is made, through which complete abdominal exploration can be accomplished and the presence and extent of abdominal metastases assessed. Next, the stomach is mobilized completely, including division of the left gastric and the left gastroepiploic arteries. The duodenum is also mobilized. The posterior surface of the stomach is completely freed, and the greater curvature is mobilized, preserving very carefully the right gastroepiploic artery. This vessel serves, subsequently, as the sole blood supply to the body of the stomach. During this procedure, the lymph-bearing tissues in the gastrohepatic ligament, and the periaortic area surrounding the celiac axis are mobilized with the stomach. A pyloroplasty, or a pyloromyotomy, is then performed. It is also helpful, during this phase of the operation, to mobilize and enlarge the esophageal hiatus.

Thoracic Portion

The next phase of the procedure is a thoracotomy, most commonly a right thoracotomy. Here the esophagus, with surrounding lymph-node tissue, is mobilized from the diaphragm to well above the gross extent of the lesion, which is then excised with an adequate margin of normal esophagus. An esophagogastric anastomosis is accomplished, high within the thoracic cavity. We feel that a plastic reconstructive procedure, at the gastroesophageal angle, is an extremely valuable adjunct. This plastic reconstruction simulates the normal gastroesophageal junction and minimizes postoperative reflux esophagitis and stricture. This procedure includes plication of the fundus of the stomach to the esophagus from the esophagogastric anastomosis superiorly 4 to 6 cm.

Indications

Malignancy of the esophagus or proximal stomach is the most common clinical indication for esophageal resection. Thirty patients with carcinoma (22 squamous-cell, eight adenocarcinoma) underwent this operation. Resection is sometimes indicated as a palliative procedure even though distant metastases can be detected preoperatively. Patients with stricture, benign tumors, perforation of the esophagus would be candidates for this procedure.

Diagnosis

Dysphasia was the most common complaint leading to the diagnosis of carcinoma of the esophagus. Twenty-nine of the 30 patients with carcinoma complained of varying degrees of difficulty swallowing. The lesion, in one case, was discovered on routine upper gastrointestinal x-rays for suspected duodenal ulcer. Esophagoscopy was performed on two patients. X-ray alone was sufficient to make the diagnosis in the other 28 patients. Dysphasia was also present in the six patients with benign disease; it was a chronic symptom in all, and had been present for over 30 years in one patient.

CASE REPORTS

Case 1

This 64-year-old lady had had dysphasia for two years. Approximately one year prior to our examination, she had had an esophagoscopy, which yielded a biopsy confirming squamous-cell carcinoma of the mid-esophagus. She was treated with cobalt irradiation, with an excellent symptomatic response for approximately eight months. Then symptoms of dysphasia reappeared, and several attempts at placement of a Mackler tube resulted in regurgitation of the tube and extreme discomfort. Resection of the esophageal lesion, with esophagogastrostomy high in the thorax, was carried out. At the time of the laparotomy, numerous liver nodules, as well as periaortic lymph-node involvement, were noted. This surgical procedure would thus be classified as a palliative resection. The lady was able to swallow on the third day post surgery and continued in a comfortable status for the next 12 months. She expired 13 months after the surgical procedure, having been ill for approximately three weeks, with gradual inanition and weakness.

Case 2

This 46-year-old gentleman represents the youngest patient in this series with carcinoma of the esophagus. He had been ill with upper abdominal discomfort for approximately four weeks, and gastrointestinal x-rays revealed a duodenal ulcer. A repeat examination, following intensive medical treatment, showed healing of the ulcer, but demonstrated a small ulcerated polypoid lesion in the distal esophagus (Figure 1). He

underwent esophageal resection and esophageal gastric anastomosis. The immediate postoperative response was satisfactory, but he expired 15 days after surgery with azotemia due to renal shut-down. Autopsy revealed the cause to be severe, chronic, preexisting renal disease, undoubtedly exacerbated by this extensive surgical procedure.

Case 3

This 59-year-old lady had suffered repeated gastrointestinal hemorrhages. She had also had symptoms of dysphasia and inability to swallow solid foods for 30 or more years. Four years prior to her esophageal resection, a Heller esophagomyotomy had been performed, which brought temporary relief from the symptoms; but severe and repeated gastrointestinal bleeding prompted re-evaluation (Figure 2). Resection of the massively dilated and hypertrophied esophagus and esophageal gastric reconstruction were carried out and she has remained symptom-free for two years.

Results

Six patients underwent the thoracic stomach operation for benign disease. Three had esophageal stricture, two achalasia,* and one, a leiomyoma of the distal esophagus. All six are well one to nine years after surgery. There were no postoperative deaths. One patient has required a single esophageal dilatation.

Thirty patients underwent the thoracic stomach operation for malignant disease (Table). Eight had an adenocarcinoma of the esophagus, or proximal stomach, while 22 were found to have squamous-cell carcinoma of the esophagus. There were four postoperative deaths immediately related to the surgical procedure. In addition, there were three late hospital deaths, including one pulmonary embolus on the 18th postoperative day, following an uneventful surgical recovery. Another patient expired following a cerebrovascular accident occurring on the 13th postoperative day. The third hospital mortality has previously been mentioned and was due to renal failure.

One patient died of causes unrelated to the surgical procedure (cerebrovascular accident) 11 months after surgery. Two weeks prior to his death there was no laboratory, clinical or x-ray evidence of metastatic disease.

Eleven patients died of metastatic tumor four to 26 months after the surgical procedure. There are three patients currently alive with evidence of metastatic tumor. *Seven patients are alive with no evidence of recurrent disease,* four of them five years or more follow-

Dead—unrelated cause (11 months)	1	3
Dead—metastatic tumor	11	36
Alive—no evidence of residual tumor	7	23
Alive with known residual tumor	3	10
Lost to follow-up	1	3
	30	
Alive—no evidence of tumor five years or more post resection	4	13

ing surgery. One patient was lost to follow-up after three months.

Comments

Ischemic necrosis of the stomach was not encountered in any of the 36 patients. In the entire group there was one anastomotic leak, which resulted in empyema and postoperative death. Twenty-four patients survived one year or more, two of them requiring esophageal dilatation. The other 22 patients were relatively asymptomatic.

The majority of these patients underwent a period or readjustment of eating habits immediately after their surgical procedure. Diarrhea, felt to be due to the vagotomy, was common, but transient. Dyspnea with full meals was not encountered. Some patients required frequent small feedings. Several needed vitamin B-12 injections to maintain a satisfactory hematocrit.

Conclusions

The overall cure rate for carcinoma of the esophagus and proximal stomach is low. Despite this low cure rate, however, this operation offers many advantages. The surviving patients are comfortable and can breathe and eat normally. Long-term complications are rare. Esophageal resection, with gastroesophageal reconstruction, also offers an excellent method for management of the benign diseases of the esophagus which are not controlled by more simple means. We feel that this operation is tolerated well enough to be used for palliation on a selective basis, even in some very ill and wasted individuals. Surgical resection of esophageal carcinoma offers the only reasonable chance for a cure from this disease.

(diphenhydramine hydrochloride)

The White band on Pink capsule combination is a registered trademark of Parke, Davis & Company.

Supplied in various dosage forms including Kapseals,® containing 50 mg. of diphenhydramine hydrochloride.

Parke, Davis & Company, Detroit, Michigan 48232

PARKE-DAVIS

No two women are quite alike...

and no other oral contraceptive is quite like Ovulen-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

The progestin is distinctive, and for some women this may mean a different clinical response. The Compack® tablet dispenser is distinctive; its functional simplicity makes it virtually patient-proof. The acceptance of Ovulen-21 is distinctive... together with Ovulen®, it is more often prescribed than any other individual contraceptive product currently available.

Indication—Oral contraception.

Contraindications—Thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia, undiagnosed abnormal genital bleeding.

Warnings—Watch for the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism, retinal thrombosis); if present or suspected discontinue the drug immediately.

British studies reported in April 1968[1,2] estimate there is a seven- to tenfold increase in mortality and morbidity due to thromboembolic diseases in women taking oral contraceptives. In these controlled retrospective studies, involving 36 reported deaths and 58 hospitalizations due to "idiopathic" thromboembolism, statistical evaluation indicated that the differences observed between users and non-users were highly significant. The conclusions reached in the studies are summarized in the table below:

Comparison of Mortality and Hospitalization Rates Due to Thromboembolic Disease in Users and Non-Users of Oral Contraceptives in Britain.

Category	Mortality Rates		Hospitalization Rates (Morbidity)
	Age 20-34	Age 35-44	Age 20-44
Users of Oral Contraceptives	1.5/100,000	3.9/100,000	47/100,000
Non-Users	0.2/100,000	0.5/100,000	5/100,000

No comparable studies are yet available in the United States. The British data, especially as they indicate the magnitude of the increased risk to the individual patient, cannot be applied directly to women in other countries in which the incidences of spontaneously occurring thromboembolic disease may differ.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or sudden onset of proptosis, diplopia or migraine. Withdraw medication if papilledema or retinal vascular lesions are found.

Since the safety of Ovulen in pregnancy has not been demonstrated, it is recommended that pregnancy be ruled out for any patient who has missed two consecutive periods before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the first missed period.

A small fraction of the hormone agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—Pretreatment physical examination should include special reference to the breasts and pelvic organs, and a Papanicolaou smear.

Endocrine and possibly liver function tests may be affected by Ovulen. Therefore, it is recommended that such tests if abnormal be repeated after the drug has been withdrawn for two months.

Pre-existing uterine fibromyomas may increase in size under the influence of progestogen-estrogen preparations.

Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation.

In breakthrough bleeding, and all irregular vaginal bleeding, consider nonfunctional causes. Adequate diagnostic measures are indicated in undiagnosed vaginal bleeding.

Carefully observe patients with a history of psychic depression and discontinue the drug if severe depression recurs.

Any possible influence of prolonged Ovulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study.

A decrease in glucose tolerance has occurred in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be observed carefully while receiving Ovulen.

Because of the effects of estrogens on epiphyseal closure Ovulen should be used judiciously in young patients in whom bone growth is not complete.

The age of the patient constitutes no absolute limiting factor, although Ovulen therapy may mask the onset of the climacteric.

The pathologist should be informed of Ovulen therapy when relevant specimens are submitted.

Adverse Reactions—A statistically significant association has been shown between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: cerebrovascular accidents, neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement, secretion), change in weight, changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, allergic rash, rise in blood pressure in susceptible individuals, mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme and nodosum, hemorrhagic eruption, itching.

The following laboratory results may be altered by oral contraceptives: hepatic function: increased sulfobromophthalein and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T^3 values; metyrapone test; pregnanediol determination.

SEARLE Where "The Pill" Began
G. D. SEARLE & CO., P. O. Box 5110, Chicago, Illinois 60680

"Breathing's a snap again," he said gingerly.
(COMPLIMENTS OF DIMETAPP)

Help clear up that miserable stuffed-up feeling with Dimetapp. Each hard-working Extentab brings welcome relief from the stuffiness, drip and congestion of upper respiratory conditions for up to 10-12 hours. Yet, patients seldom experience drowsiness or overstimulation. The key to success is the Dimetapp formula: Dimetane (brompheniramine maleate)—along with phenylephrine and phenylpropanolamine, two time-tested decongestants. They get the job done... in a hurry.

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripheral vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

Editorials

Whipple's Disease

WHIPPLE'S DISEASE or intestinal lipodystrophy was considered a rare and incurable disease until recently. The etiology was unknown and the diagnosis could be confirmed only at laparotomy or autopsy. These concepts have been radically altered by observations made within the past few years as illustrated by the interesting case report of Bornstein, Theologides and Kennedy* in this issue of MINNESOTA MEDICINE.

As with other diseases of the small bowel, the study of Whipple's disease was greatly facilitated by the introduction and application of safe and effective intestinal biopsy technics. In 1958, Bolt et al.[1] reported the first case of Whipple's disease diagnosed in this manner, and by 1961 the tiny red-shaped structures in the lamina propria, described initially by Whipple in 1907, were found to have the ultra structural characteristics of bacilli.[2,3]

Simultaneously, clinical observations suggested that remissions could be induced by antibiotic therapy,[4] and subsequent study has shown that the bacilliform bodies of Whipple's disease disappear from the intestinal mucosa after appropriate therapy with antibiotics.[5] When serial biopsies were taken after an antibiotic-induced remission, it was found that the bacilli may reappear and, in the absence of further treatment, this was followed by clinical relapse. These observations are suggestive of an infectious etiology of Whipples disease.

Peroral intestinal biopsy is the diagnostic procedure of choice. Occasionally the diagnosis can be made by biopsy of a lymph node or the colon. Radiographic findings may be suggestive but are not diagnostic. In view of the potential curability of Whipple's disease, it should be considered in any patient with unexplained progressive wasting when coupled with malabsorption, lymphadenopathy or arthritis. Undoubtedly, the increasing clinical use of peroral biopsy of the small bowel will uncover cases of Whipple's disease before the clinical picture is entirely developed.

Current treatment consists of antibiotic therapy for a period of months. A regimen of 1,200,000 U. procaine penicillin G. and 1 gm. streptomycin daily for 10 to 14 days followed by tetracycline 1 gm. daily for 10 to 12 months has been effective.[6] Serial intestinal biopsies may prove useful in the evaluation of therapeutic success and in the prediction of relapse. Clinical remission is generally prompt and striking, as with the patient of Bornstein et al., although exacerbations have been reported after apparently inadequate antibiotic therapy.[5] In one case the organism appeared to show resistance to tetracycline but penicillin seemed effective. Corticosteroid therapy does not seem necessary although it has been useful in the treatment of persisting arthritis.

BETTMAN ARCHIVE

Just one tablet at bedtime • Prevents painful night leg cramps • Permits restful sleep

How many of your patients stamp their feet at night and lose sleep because of painful leg cramps? Unless prompted, they usually fail to report this distressing condition and suffer needlessly.

One tablet of QUINAMM at bedtime usually controls distressing night cramps and permits restful sleep with the initial dose.

Prescribing information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Side Effects/Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

A·H·ROBINS

Inappropriate Secretion of Antidiuretic Hormone and Inappropriate Thirst

HYPONATREMIA, NATRIURESIS, and the inability to excrete a maximally dilute urine are hallmarks of the syndrome of inappropriate secretion of antidiuretic hormone. Their importance has been stressed since Schwartz and associates[1] first described the syndrome in 1957. The inability to excrete water normally is reflected in the formation of urine which is less than maximally dilute (and usually is hyperosmolar to serum) in the presence of hypo-osmolality of the serum and extracellular fluid. The hyponatremia cannot be corrected by dietary sodium supplements because natriuresis persists and sodium is lost, almost milligram for milligram, as it is administered. These abnormalities can be explained on the basis of an expanded extracellular fluid space and are accounted for by one or a combination of the following factors.

1. Increased glomerular filtration rate may occur with an expanded extracellular fluid space. This presents to the renal tubule extra sodium which is available for excretion. However, it has been amply demonstrated that natriuresis can still occur even if the renal artery is partially occluded, preventing an increased glomerular filtration rate.

2. Aldosterone excretion and secretion are reduced by an expanded extracellular fluid space, thereby encouraging the excretion of filtered sodium. But the administration of a full replacement dose (or more) of a potent mineralocorticoid does not prevent the sodium loss. In addition, when measured, aldosterone secretion and excretion have almost invariably been normal in this syndrome. Since neither of these first two factors can adequately explain the natriuresis, a "third factor" must be operative.

3. This third factor effect, mediated by a presumed humoral (or hormonal) agent of central nervous system origin, reduces the proportion of sodium reabsorbed in the proximal renal tubule in response to expansion of the extracellular fluid . This may occur even when the glomerular filtration rate is experimentally reduced or when mineralocorticoid is available in more than physiologic quantities.

4. Recent evidence[2] has suggested that the influence of antidiuretic hormone on membrane permeability may encourage sodium migration from an extracellular to an intracellular site, thus contributing to the hyponatremia.

The prime abnormality—namely, an expanded extracellular fluid space—is attributable to the excessive and inappropriate secretion of antidiuretic hormone. The renal loss of sodium cannot be explained by a direct action of antidiuretic hormone because, if the fluid intake is restricted so that water retention and weight gain do not occur, the serum remains normotonic with a normal sodium concentration. All the abnormalities of the syndrome can be easily reversed by the simple expedient of restricting fluid intake.

Very properly, Segar and Moore* have questioned the source of the "inappropriate thirst" that provides the water for overexpansion of the extracellular fluid space. Heretofore, this important aspect of the syndrome has not been emphasized; it raises significant questions regarding the physiologic control of so basic an urge as thirst. Hyperosmolality and hypovolemia result in thirst and are also associated with increased blood levels of antidiuretic hormone. Conversely, hypo-osmolality with an expanded extracellular fluid space is associated with suppression of antidiuretic hormone secretion and an increased excretion of free water. Thirst, however, is not necessarily diminished under these circumstances, and it is only the efficiency of the normal excretory mechanism for water that prevents the frequent occurrence of self-induced water intoxication. When the normal mechanism of water excretion is absent, as in the presence of excessive, nonsuppressible, inappropriate secretion of antidiuretic hormone, voluntary excessive fluid intake quickly leads to overexpansion of the extracellular fluid space with its resultant complications. Under these circumstances, there seems to be no control mecha-

*Segar, W. E., and Moore, W. W.: Hyponatremia: Increased Antidiuretic Hormone and "Inappropriate" Thirst in a Patient with Bronchogenic Carcinoma. Minnesota Med 51:625, 1968.

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

Contraindications: Glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal or bladder neck obstruction.

Precautions: Use cautiously in the presence of hypertension, hyperthyroidism, coronary artery disease; warn vehicle or machine operators of possible drowsiness.

Usage in Pregnancy: Use in pregnancy, nursing mothers and women who might bear children only when potential benefits have been weighed against possible hazards.

Note: The iodine in isopropamide iodide may alter PBI test results and will suppress I^{131} uptake; discontinue 'Ornade' one week before these tests.

Adverse Reactions: Drowsiness; excessive dryness of nose, throat or mouth; nervousness; insomnia. Other known possible adverse reactions of the individual ingredients: nausea, vomiting, diarrhea, rash, dizziness, fatigue, tightness of chest, abdominal pain, irritability, tachycardia, headache, incoordination, tremor, difficulty in urination. Thrombocytopenia, leukopenia and convulsions have been reported.

Supplied: Bottles of 50 capsules.

a stuffy nose is no laughing matter

nism to prevent the unnecessary ingestion of water and to curtail the inappropriate thirst. Most intriguing of the authors' suggestions to explain this phenomenon is the conjecture that an increased antidiuretic hormone level in the blood is in itself a thirst-producing stimulus.

The authors are to be congratulated for emphasizing the importance of abnormal fluid ingestion in the development of the full syndrome of inappropriate secretion of antidiuretic hormone, a facet previously ignored. In addition, they have indicated an important hiatus in our knowledge of physiology of fluid volume control—namely, the mechanism of thirst regulation.

Elusive Coarctation of the Aorta

THE REPORT of 18 cases of coarctation of the aorta in veterans by Sako and Beard[1] serves well to remind physicians of the possibility of overlooking this relatively easily diagnosed condition.

Since most of us have both undergone and given camp, preinduction, and discharge physical examinations in the typical crowded and noisy gymnasium, we are not too surprised at rather salient conditions being missed. On the other hand, in a most interesting clinicopathologic conference, another case reported in the October 1967 issue of *American Heart Journal* points out the difficulties encountered in the differential diagnosis under ideal circumstances of examination.

Interest in the mechanism of production of hypertension and the rather unique lack of resultant disease of the small vessels in coarctation has brought forth important articles in the recent literature. Several workers have shown normal renal blood flow and angiotensin levels, although Sealy[2] cited two cases in which angiotensin levels that were high before operation fell to normal after repair of the coarctation. Postoperative hypertension, especially diastolic, is common and may be associated with gastrointestinal symptoms secondary to ischemia and necrosis of the small bowel; both the hypertension and the gastrointestinal symptoms may be reversed with suitable antihypertensive therapy. The hypertension apparently results from increased response of vessels below the coarctation to the stress-induced elevation of norepinephrine.[3]

These recent studies suggest that the hypertension associated with coarctation results from both humoral and reflex factors, which adjust baroreceptors to hypertensive levels in order to maintain sufficient pressure above the obstruction and assure adequate flow beyond it.

Pathology

Ugliness is a point of view: an ulcer is wonderful to a pathologist.—Austin O'Malley

Dilantin®
(diphenylhydantoin)

PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.

DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anticonvulsant drugs.
PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. ADVERSE REACTIONS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred.
DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.
Parke, Davis & Company, Detroit, Michigan 48232

The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

PARKE-DAVIS 018R67

Scalene Node Resection or Mediastinoscopy and Biopsy*

In 1959 MEDIASTINOSCOPY became a new diagnostic technique in unknown mediastinal or pulmonary disease. Extensive experience has proven the value and safety of this procedure. In many instances, mediastinoscopy should supplant scalene node resection as the diagnostic approach. There are ample statistics that indicate mediastinoscopy and biopsy obtain more positive tissue diagnoses for nonneoplastic and neoplastic disease than does scalene node examination.

However, *I most heartily disagree* with the statement that scalene node removal involves more morbidity and mortality than does mediastinoscopy. This latter statement results from several reports in the literature.[1,2] Review of these reports and others[3] indicates that the major causes of operative morbidity and mortality are technical errors during the procedure. Injury to major vessels, nerves, and lymphatics as well as air embolism have occurred. In most part technical failures resulted because the surgical procedure was delegated to an unskilled, untrained, and unsupervised house officer to do "a little biopsy." This important fact is noted in the reports. The same technical failures would erupt if mediastinoscopy were entrusted to the untrained, unsupervised individual.

There are specific indications for mediastinoscopy and/or scalene removal. Each remains a valuable diagnostic technique. Both procedures are complicated technical dissections that require the best of surgical skills. Both are equally safe.

Another misinterpreted statement concerns "resectability" of pulmonary neoplasms. The term "resectability" needs further clarification. "Resectability" for cure and a positive node biopsy for metastases by mediastinoscopy are *not* incompatible. It should *not* be assumed that a positive biopsy contraindicates (and "saves the patient" from) thoracotomy. Indeed, if this is the attitude, a sizable percentage of patients will be condemned in the effort to "save" them. I would refer interested readers to an excellent article by N. P. Bergh and T. Schersten.[4]

Patients with neoplasm fall into certain categories which can be determined by conventional x-rays and laminograms in most instances. Careful teamwork between the physician, surgeon, radiologist, oncologist, and pathologist will give the afflicted patient the best opportunity for a future.

Salt used to be an all or nothing proposition. Now, there's a happy compromise.

When you tell your patients to cut down on sodium, they have to settle for less than tasty meals. That takes a lot of will power. Now there's new Morton Half/Salt Mixture™. It contains half the sodium of regular salt so your patients can cut down on salt without cutting it out. But, they still get all the satisfaction of true salt flavor. You'll find that new Morton Half/Salt Mixture is far more dependable than will power. And, it makes low-sodium diets a lot easier for your patients to swallow.

Permanent Transvenous Cardiac Pacing*

THE DEVELOPMENT of permanent transvenous electrodes with implantable pulse-generator packs has provided a means of cardiac pacing that does not require a major operative procedure for the insertion of the electrodes. Under local anesthesia, the electrode is inserted into the external or internal jugular vein and advanced to the apex of the right ventricle. Fluoroscopic control is necessary for accurate positioning of the electrode tip. The pulse generator is placed in a pocket in the anterior chest wall. This procedure can be performed as the initial procedure in a patient requiring long-term cardiac pacing, without the preliminary insertion of a temporary pacer as is required when epicardial electrodes are used. The indications for cardiac pacing can now be extended to include those patients who require pacing but are considered to be poor risks for the major operative procedure required to implant epicardial electrodes.

Complications have been reported, as enumerated by Bilgutay and associates. Embolic episodes are uncommon and anticoagulant therapy is not necessary. Infection can usually be avoided by aseptic technique at the time of insertion, but this requires careful attention when the availability of fluoroscopy requires that the procedure be performed in areas other than the operating room. Erosion of an electrode through the skin usually occurs where the electrodes cross the clavicle and can be avoided if the electrode passes under the clavicle, especially in thin patients.

Accurate placement of the electrode tip allows effective and continuous pacing without perforation of the ventricle. In our experience, fracture of transvenous electrodes has occurred with less frequency than fracture of epicardial electrodes.

The complication of incarceration of an electrode in the trabeculae of the right ventricle is not common, because permanent electrodes seldom require removal. The successful removal of an incarcerated electrode by the method described by Bilgutay and associates obviates the need for a major operation which frequently would not be tolerated by patients who had been selected for transvenous pacing.

Is it depression?
He says "It's my stomach..."

...but his other symptoms: functional somatic complaints, anxiety, insomnia, anorexia, feelings of guilt strongly suggest an underlying depression.

when the diagnosis is depression

ELAVIL® HCl
(AMITRIPTYLINE HCl | MSD)

Indications: Mental depression and mild anxiety accompanying depression.

Contraindications: Glaucoma and predisposition to urinary retention. Not recommended in pregnancy.

Precautions and Side Effects: Drowsiness may occur within the first few days of therapy. Patients should be warned against driving a car or operating machinery or appliances requiring alert attention. When depression is accompanied by anxiety or agitation too severe to be controlled by ELAVIL HCl alone, a phenothiazine tranquilizer may be given concomitantly. Suicide is always a possibility in mental depression and may remain until significant remission occurs. Supervise patients closely in case they may require hospitalization or concomitant electroshock therapy. Untoward reactions have been reported after the combined use of antidepressant agents having varying modes of activity. Accordingly, consider possibility of potentiation in combined use of antidepressants. Monoamine oxidase inhibitor drugs may potentiate other drugs and such potentiation may even cause death; permit at least two weeks to elapse between administration of two agents; in such patients, initiate therapy with ELAVIL HCl cautiously with gradual increase in dosage required to obtain a satisfactory response. Caution patients about errors of judgment due to change in mood, and that the response to alcohol may be potentiated. May provoke mania or hypomania in manic-depressive patients.

Side effects include drowsiness; dizziness; nausea; excitement; hypotension; fine tremor; jitteriness; weakness; headache; heartburn; anorexia; increased perspiration; incoordination; allergic-type reactions manifested by skin rash, swelling of face and tongue, itching; numbness and tingling of limbs, including peripheral neuropathy; activation of schizophrenia which may require phenothiazine tranquilizer therapy; epileptiform seizures in chronic schizophrenics; temporary confusion, disturbed concentration or, rarely, transient visual hallucinations on high doses; evidence of anticholinergic activity, such as tachycardia, dryness of the mouth, blurring of vision, urinary retention, constipation; paralytic ileus; jaundice; agranulocytosis.

Careful observation of all patients is recommended. The antidepressant activity may be evident within 3 or 4 days or may take as long as 30 days to develop adequately, and lack of response sometimes occurs. Response to medication will vary according to severity as well as type of depression present. Elderly patients and adolescents can often be managed on lower dosage levels.

Supplied: Tablets ELAVIL HCl, containing 10 mg., 25 mg., and 50 mg. amitriptyline HCl, bottles of 100 and 1000; Injection ELAVIL HCl, in 10-cc. vials, containing per cc.: 10 mg. amitriptyline HCl, 44 mg. dextrose, 1.5 mg. methylparaben, and 0.2 mg. propylparaben.

WHERE TODAY'S THEORY IS TOMORROW'S THERAPY

You May Be Right

There Was A Time

There was a time when childbirth and pregnancy were accompanied by grave dangers; when toxemia, infection and hemorrhage were commonplace and carried many young mothers to an untimely grave—and yet society forbade fetal destruction.

There was a time when syphilis was often transmitted from the infected mother to her unborn child, inflicting on this innocent victim lifelong physical disfigurement and heartbreaking handicaps—and yet society forbade termination of pregnancy, and instead gave encouragement to the medical profession making mandatory the early recognition and prompt treatment of all syphilitic mothers to prevent this tragedy.

There was a time when there were no reliable or acceptable methods of contraception, and without doubt the vast majority of pregnancies were unplanned and many quite inconvenient—and yet society protected the fetus against arbitrary destruction because it came upon the scene unsummoned.

There was a time when Rh isoimmunization wreaked untold havoc upon many babies, silently and without detectable warning. Now the process can be detected in the incipient stage, monitored in its progression, and thwarted by prompt intervention in nearly all cases. And within the past year, this tragic process has been found completely preventable by prompt immunization of the Rh negative mother with anti-Rh immune globulin. This substance is now universally available.

There was a time when the Rubella virus (German measles) infected a small percentage of pregnant mothers and occasionally damaged the fetus, sometimes severely, and there was no way of telling which mother was susceptible or of preventing the contagion. Now there is available a test showing which mother is susceptible to Rubella. Next year a vaccine to immunize against Rubella is expected. There need be no more Rubella babies.

There was a time when the additional burden of pregnancy was thought detrimental to the mother with heart disease, kidney disease, tuberculosis, or liver dysfunction. With the rapid technologic advance in controlling these diseases, pregnancy no longer constitutes an additional hazard.

Why then, in 1968, are we suddenly being told to ignore the foregoing medical progress and to exhibit less reverence for life than our preceding generations? Now that conception is purely optional, now that pregnancy and childbirth are unprecedentedly safe and comfortable, now that our society is more affluent than any in the history of man, why is it that volitional fetal destruction should be urged as an enlightened and progressive step? Have past generations stood firm against fetal destruction out of callous indifference to human suffering, or out of a deeply mature and fundamental reverence for life, including the right to live? As the medical indications for therapeutic abortion have been eliminated, only the psycho-social and economic

Smiles speak louder than words

for the good taste of Soyalac

Milk-free, hypo-allergenic Soyalac has a pleasing taste that is eagerly accepted by most infants. It's similar to mother's milk in composition and assimilation, much like cow's milk in consistency and completely free of fibre. Extensive clinical data support Soyalac's value in promoting growth and development. Soyalac is also excellent for growing children and adults.

indications remain; so why call this a medical problem. It is a social problem —an economic problem—but most of all, a problem of conscience. The society which encourages optional destruction of its offspring is not liberal, progressive or enlightened. It is instead hedonistic,* self-centered, and sick.

Proponents of popularizing legal abortion have found their most passionate argument to be the predicament of the innocent victim of rape or incest. Several facts must be set forth to put this problem in proper perspective. First, the transgression seldom occurs adjacent to ovulation, for the fertile time is but a small fraction of each month. Secondly, clinicians of wide experience have been repeatedly impressed with the rarity that conception follows an assault even at the theoretically fertile time. Finally, in the event that rape or incest is known to have occurred with certainty, two choices are available to the physician within the present scope of his license. He can prescribe an estrogenic substance for five days, rendering the uterine lining unsuitable for implantation, or he can remove the uterine lining by a simple dilatation and curettage. In either case, whether the ovum was fertilized is never known. Its ultimate "nesting site" having been denied pregnancy does not occur.

Where rape or incest is concealed, and only later alleged to have occurred, the need for deliberate investigation, careful documentation, and judicial decision is too obvious for comment. Rarely could these facts be assembled and properly weighed before the fetus was of such an age that destruction could no longer be called abortion. It would have to be termed destruction of a theoretically viable infant, and a stillbirth certificate would be required. In short, infanticide rather than abortion would be performed.

In summary, then, if society chooses to popularize legal abortion, let it not hide behind the pretext of rape, incest, or diseases which in the past proved uncontrollable. Let it forthrightly state that it intends to invite this procedure as a social convenience. But then let no one call this new, or progressive, or civilized, for it is none of these. It will be tacit public admission of our failure to take individual responsibility as members of society; and this is more than just regrettable; it is historically retrogressive, immature, and in the long run destructive of the integrity of our basic unit of society—the family.

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In tetracycline-sensitive bacterial infection complicating respiratory allergy, ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Contraindications: Hypersensitivity to any component.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Drowsiness, anorexia, slight gastric distress can occur. In excessive drowsiness, consider longer dosage intervals. Persons on full dosage should not operate vehicles. Nonsusceptible organisms may overgrow; treat superinfection appropriately. Treat beta-hemolytic streptococcal infections at least 10 days to help prevent rheumatic fever or acute glomerulonephritis. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Adverse Reactions: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity* reactions—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

Lederle

The Editor's Soliloquy

Elbow Steering

"How old are you?"
"About your age!"
"The 'ell you are!"
"The 'ell I aint!"
With that retort the datum seeking ended abruptly.

True, there are a few occasions when one must disclose his vital statistics: age, sex, medical history, driver's license credentials, life insurance data for the purpose of extrapolating probable longevity, eligibility to vote, collect social security, and hold political office,—well, that's about it! Otherwise, why date a man! If he is youthful and flexible in body and mind, he is young—chronology notwithstanding.

The compulsive reasons for wanting to know a man's age doubtless run the gamut from idle curiosity to idol worship. But whatever the reason, knowing the ages of your friends and associates has no more value than knowing the color of their knee joints. Who could care less!

I scarcely know the age of my own children. I know their birth *days;* but their birth *dates* don't concern me. Though a generation removed, they are my contemporaries, with whom I visit, discuss, socialize, philosophize, ski, dance the Watusi, hunt, fish, laugh and cry. Likewise the ages of my confreres are equally irrelevant within my frame of reference.

I can walk unassisted—without the guidance of someone beside me. Arm-in-arm camaraderie—yes; but elbow steering—no tank you!

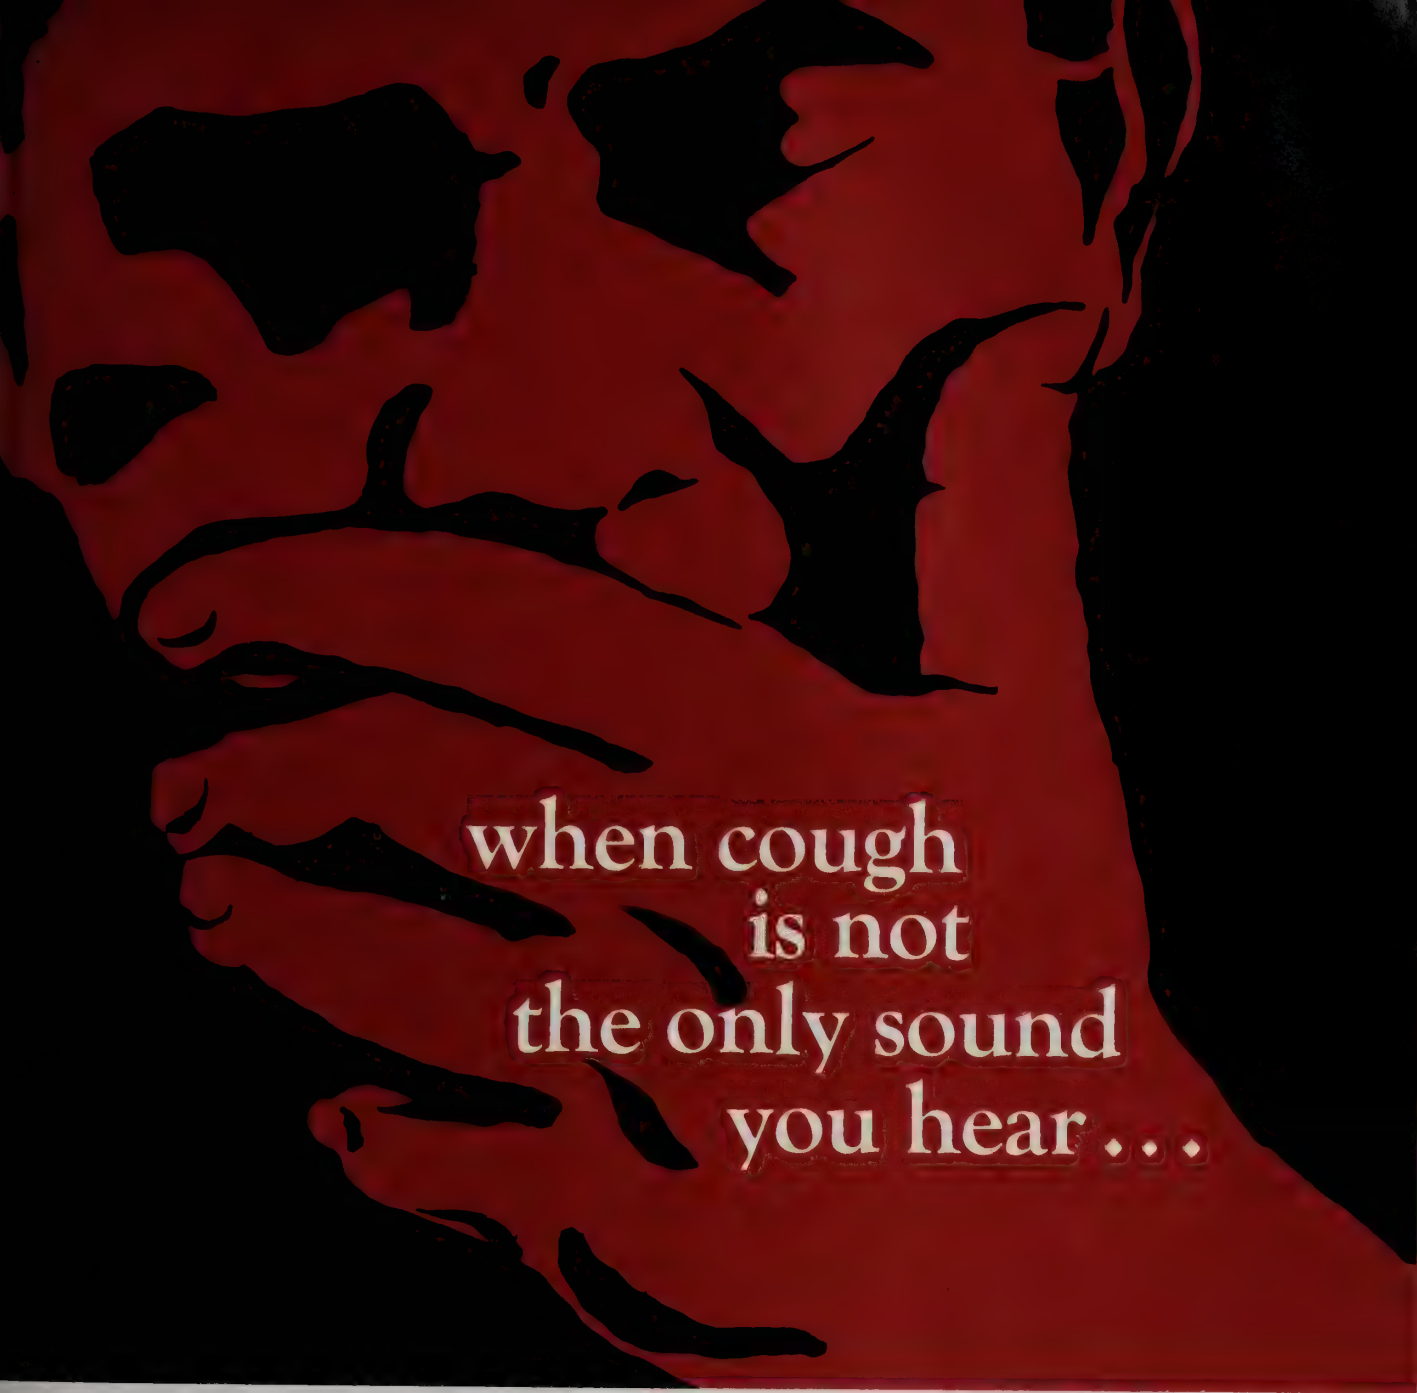
Letter to the Editor

Dr. Charles Lick was up to see me regarding what he termed a misinterpretation of his case report as published in MINNESOTA MEDICINE in June 1968*— I don't know if you want to contact him on this or not but it would be a very gracious thing to do.

John H. Moe, M.D.

*Page 809.



Dear Dr. Lick:

I have received the enclosed correspondence from Dr. John H. Moe and I sincerely regret that MINNESOTA MEDICINE misinterpreted your case report which should have stated in part, "Discussed the matter with Dr. Bell, who suggested that amputation should be considered. Called two experts in who advised amputation at the shoulder. Husband refused. I discussed the matter with her husband of a lesser procedure—that of removing the tumor with a liberal area of the radius above and below the tumor, to be followed by a radial transplant, a length enough to be a trifle longer than the gap. This was agreed upon by the husband—"

I am indeed sorry and hope that it has not caused too much inconvenience.

OMNI-TUSS® b.i.d.

. . . **because** OMNI-TUSS is indicated for cough associated with upper respiratory tract infections, bronchitis, bronchiectasis, bronchial asthma, emphysema, sinusitis and rhinitis, hay fever, or other allergic conditions. Any of these conditions may exhibit the general symptom syndrome—coughing, wheezing, bronchospasm, and tenacious mucus—which may benefit from the antitussive, bronchodilative, antihistaminic, and expectorant action of Omni-Tuss.

The therapeutic usefulness of Omni-Tuss is enhanced by a unique resin complex formulation providing the clinically desirable advantages of: (1) uniform drug availability throughout an extended period, (2) 8 to 12 hours of symptomatic control, (3) minimal dosage requirement, (4) minimal side effects.

Economical, efficient **b.i.d.** dosage—extremely well-tolerated by children, 6-12, and adults.

'Omni Tuss' Suspension: Each teaspoonful (5 cc.) contains 10 mg. codeine (Warning: May be habit-forming), 5 mg. phenyltoloxamine, 3 mg. chlorpheniramine, 25 mg. ephedrine, all as cation exchange resin complexes of sulfonated polystyrene, and 20 mg. guaiacol carbonate.

Available on prescription only. Class X exempt narcotic. Permissible on oral prescription.

Dosage: *Adults:* 1 teaspoonful (5 cc.) q12h.
Children (6-12 *years*): ½ teaspoonful q12h.

Side Effects: Minimal, but when encountered may include jitteriness, nausea, drying of mouth, insomnia, constipation, which disappear upon adjustment of the dose or discontinuance of treatment.

Precautions and Contraindications: For complete detailed information, refer to package insert or official brochure.

In the complex picture of moderate to severe anxiety...

there is a new reason for prescribing Mellaril (Thioridazine HCl)

effectiveness in mixed anxiety-depression

Long recognized for its usefulness in the treatment of moderate to severe anxiety, Mellaril is now also known to be effective against mixed anxiety-depression.

Often the symptoms of anxiety states are difficult to sort out—even with the most careful probing. The patient may manifest symptoms of agitation, restlessness, insomnia, somatic complaints. But what of the depression that may be mixed in the total picture? It is reassuring to know that Mellaril may be prescribed—with strong possibilities of success—when there is anxiety alone or a mixture of anxiety and depression.

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine hydrochloride). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

"The inconvenience of a cold"

For a cold, NTZ® Nasal Spray provides rapid relief of nasal symptoms. Relief starts with the first spray which opens the inferior part of the common meatus. A second spray, a few minutes later, will shrink the turbinates to help provide sinus drainage and ventilation. Dosage may be repeated every three or four hours as needed, for temporary relief of symptoms. NTZ is well tolerated but overdosage should be avoided.

As a sinusitis deterrent, NTZ Nasal Spray can be used to keep the nasal passages open during a cold to help prevent development of acute sinusitis—or to help prevent the acute condition from becoming chronic.

Supplied: NTZ Nasal Spray, plastic squeeze bottles of 20 ml.; NTZ Nasal Solution, bottles of 30 ml. (1 fl. oz.) with dropper.

NTZ is more than a simple vasoconstrictor. It contains

Neo-Synephrine® (brand of phenylephrine) HCl 0.5 per cent, the major component, virtually synonymous with fast, efficient but gentle nasal vasoconstriction.

Thenfadil® (brand of thenyldiamine) HCl 0.1 per cent, topical antihistamine for reduction of rhinorrhea, sneezing or itching. It combats the allergic reactions that may occur in colds or sinusitis.

Zephiran® (brand of benzalkonium, as chloride, refined) 1:5000, antiseptic preservative and wetting agent to promote penetration and spread of the formula.

Curbstone Consultation

INDIRECT MEASURMENT OF BLOOD PRESSURE

QUESTION: Are there any methods presently available for the indirect measurement of blood pressure?

ANSWER: Yes. A method has been developed by Dr. Ray Ware and associates of Southwest Research Institute in San Antonio for measurement of blood pressure indirectly utilizing the Doppler principle* to detect movement of the artery occurring as a result of the pressure pulse caused by the expulsion of blood from the heart. The ultrasonic† detector, attached to the inner side of the blood pressure cuff, directs a narrow, ultrasonic beam through the patient's arm (leg) to the artery. If the artery is not moving, as would be the case with full occlusion, the frequency of the reflected beam would remain constant. When the beam is reflected from a moving artery its frequency changes and is detected and converted to a sound or to a deflection on a recorder.

As the cuff pressure is slowly released, a pressure is reached (systolic pressure) that is great enough to force open the occluded artery. This causes a single sound or deflection on the recorder and is analogous to the onset of the Korotkoff sounds. As the cuff pressure is further reduced, sounds or deflections of longer duration occur, caused by a larger percentage of the pressure pulse forcing its way through the occluded artery. When the cuff pressure is reduced to the point where the sounds or the deflections become continuous, diastolic pressure has been reached. This is analogous to the disappearance of the Korotkoff sounds. Although still in the experimental stage, the measurements made with it correlate closely with intra-arterial pressure measurements, and it thus holds great promise for future clinical use.

Refuse to be ill. Never tell people you are ill; never own it to yourself. Illness is one of those things which a man should resist on principle at the onset.—Bulwer-Lytton

Q. How much does the **anticostive*** **hematinic** cost?

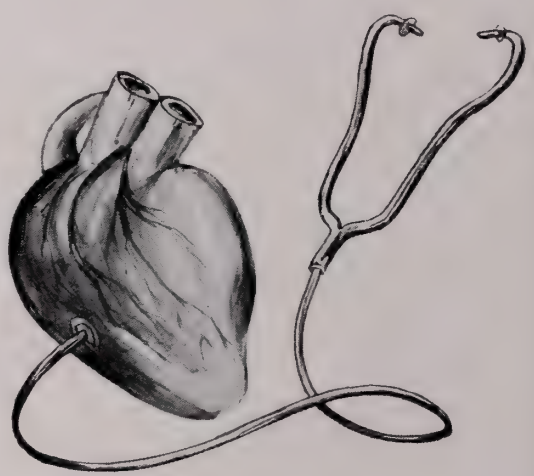
A. No more than costive hematinics cost!

The anticostive hematinic is

PERITINIC®

Hematinic with Vitamins and Fecal Softener

A tablet-a-day provides:



● Elemental Iron (as Ferrous Fumarate)	100 mg
● Dioctyl Sodium Sulfosuccinate (to counteract constipating effect of iron)	100 mg
Vitamin B_1	7.5 mg
Vitamin B_2	7.5 mg
Vitamin B_6	7.5 mg
Vitamin B_{12}	50 mcgm
Vitamin C	200 mg
Niacinamide	30 mg
Folic Acid	0.05 mg
Pantothenic Acid	15 mg

Bottles of 60

* anticostive, *adj.* (*anti* opposed to + *costive* causing constipation.) Against constipation. Now isn't that a good idea in an iron-containing hematinic?

Diagnosis: Diabetes mellitus.

Note the marked calcification of the vas deferens on each side (arrows). This calcification is almost pathognomonic of diabetes mellitus. Tuberculous infection of the genitourinary tract has been described as a cause of radiographic calcification of the vas but this is much less common as an etiologic factor than is diabetes.

Degenerative osteophyte formation in the lumbar spine and calcification of some of the pelvic blood vessels is also seen. Vascular calcification is a common finding in diabetes of long standing but is not specific and not too helpful in making the diagnosis unless the patient is under the age of 40 years.

Calcification of the vas deferens was first reported by Bianchini in 1930. In 1951 Wilson and Marks reported 60 cases of calcified vas deferens; of these, 56 were in diabetics of long standing. More recently, Kellett reported 215 cases, 98% of which were in diabetics.

The physiologic mechanism of this calcification in the muscular wall of the vas in diabetics is unknown but is felt to be related to the degenerative process associated with diabetes. Most, but not all of these patients are said to be impotent.

Fracture Conference

Severe Fractures of the Ankle*

Dr. Lee C. Detenbeck:†

The subject of this fracture conference is methods of treatment for various severe fractures involving the ankle joint. Two cases will be presented. Case 1 is that of a 68-year-old farmer who sustained a fracture of his right ankle in December 1965, when a tractor rolled over on his leg (Figure 1). Essentially this is a trimalleolar fracture of the right ankle. The circulation is intact; both pedal pulses are present. The ankle was treated by injection of a local anesthetic agent into the fracture site and reduction of the fracture in the emergency room by realigning the foot with the tibia and gently molding the medial and lateral malleoli into proper position.

Dr. William H. Bickel:‡

The point to be made is that he had this trimalleolar fracture because he had intact ligaments. If the ligaments are ruptured, no fractures result in most cases. So it is always desirable to do just as was done in this instance: try to use the intact ligaments to pull the disrupted bony fragments back into line. Often with proper manipulation of the ankle they will fall in line just as they have here. This is an excellent reduction. I would accept it as it is.

While we are talking about trimalleolar fractures we should mention that the term "trimalleolar" is one Dr. M. S. Henderson coined in an article he published in the *Wisconsin Journal of Medicine* about 1938. He recognized the posterior flare of the distal tibia as the "third malleolus." The external and internal malleoli are obvious. He also discussed the fact that in trimalleolar fracture the ligaments are intact and the disrupted bone surfaces will follow the ligaments if one manipulates the foot into proper alignment with the leg. Sometimes this does not happen; then one can resort to an open reduction.

---

*Fracture conference held March 18, 1968.

†Mayo Graduate School of Medicine (University of Minnesota), Resident in Orthopedic Surgery.

‡Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

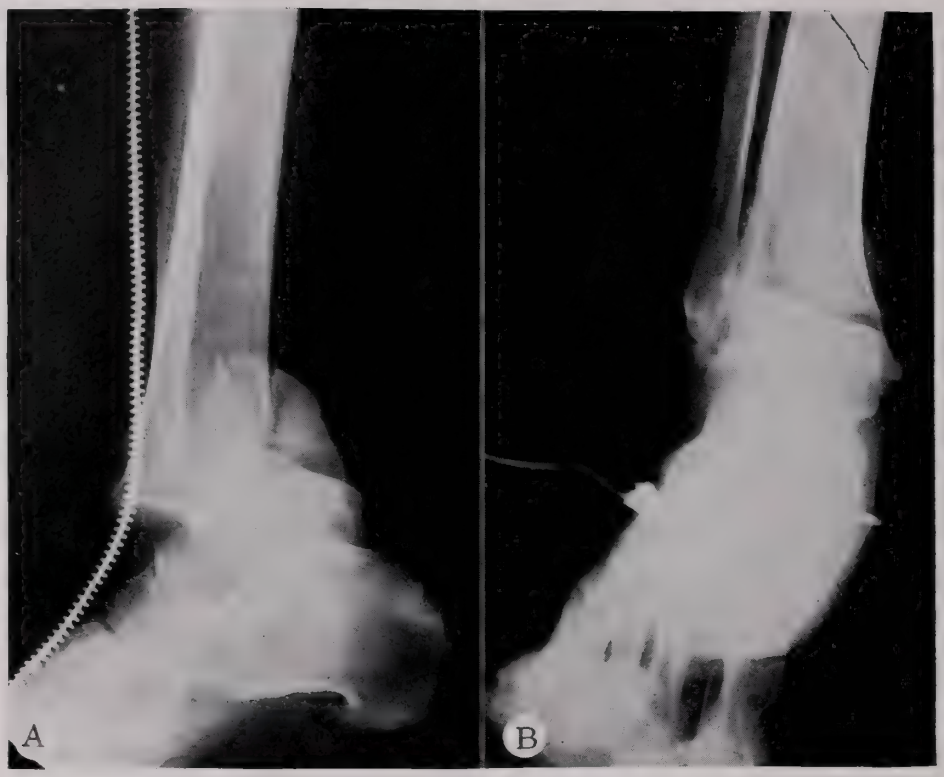

Fig. 1 (Case 1)—A and B, Acute fracture-dislocation of right ankle.

See page 1470 for Figure 1C and D, After closed reduction. Reduction is accepted.

(Authors sent figure in too late for inclusion in article, but asked that it be published elsewhere in journal.)

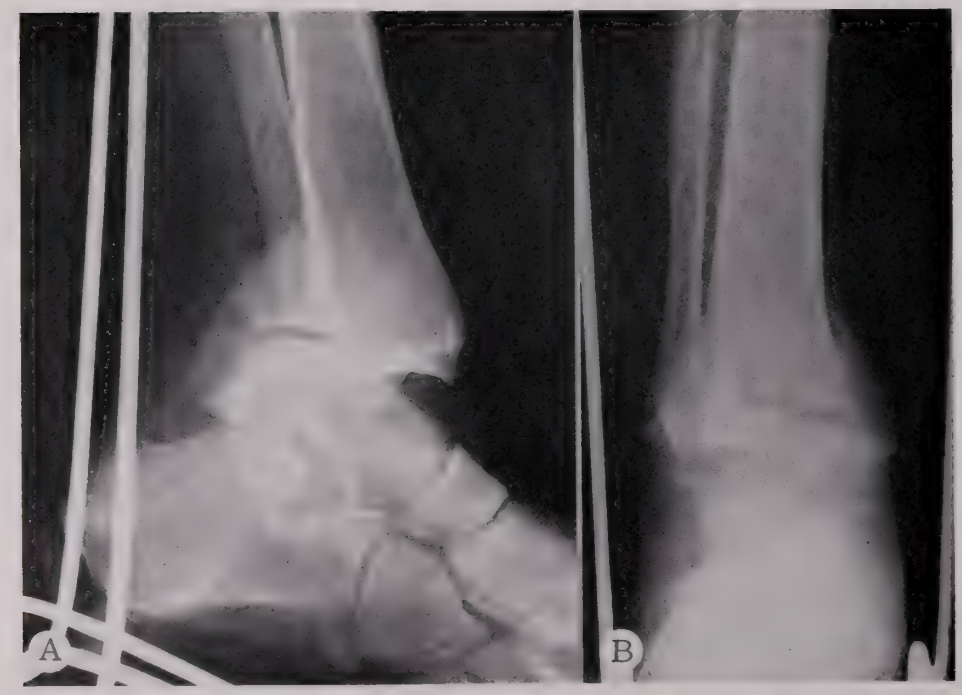

Fig. 2 (Case 1)—A and B, Three days after closed reduction. Note that position has been lost. Open reduction was necessary.

Dr. Detenbeck:

Roentgenograms made three days later revealed loss of the reduction and a return to the dislocated state. Open reduction seemed to be indicated, and four days after the fracture, open reduction and internal fixation of the internal malleolus were carried out, with the application of a long leg cast (Figure 2).

Dr. Mark B. Coventry:*

I wish we had a roentgenogram of the other ankle. This is an odd-looking ankle; there is something different about it. The talus is very broad. Is there any comment on it by the radiologist?

Dr. Ray E. Santos:†

I reduced this fracture in the emergency room and thought that things had turned out quite well. However, Dr. Bickel told me the next morning, "It will never hold. It will never stay there. I'll show you in a few days." Three days later, on re-x-ray examination, my fine reduction had "evaporated."

Dr. Coventry:

How did you hold the fracture from the time of reduction in the operating room until three days later?

Dr. Santos:

We held it in a modified Robert Jones dressing. That is where we made our mistake—the use of a dressing with so much padding that maintenance of the fragments was not possible.

Dr. Coventry:

I would not exactly blame the fracture. If you had put it in a good cast and bivalved it right away, maybe it would have remained reduced.

Dr. Santos:

We thought that there was so much swelling and ecchymosis that use of a cast at that time would not be safe. I know that the Robert Jones dressing is certainly not adequate fixation. We had a lot of difficulty with the posterior malleolus in trying to get it restored anatomically.

Dr. Bickel:

Holding it down, you mean?

Dr. Santos:

Yes.

Dr. Bickel:

On occasion, dorsiflexion of the great toe, putting tension on the long flexor, will help reduce and hold the posterior malleolus. What about the other ankle?

Dr. Santos:

We did not x-ray it.

---

*Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

†Mayo Graduate School of Medicine (University of Minnesota), Rochester; Resident in Orthopedic Surgery.

Dr. Coventry:

Were you ever concerned that this looked different from the average fracture?

Dr. Santos:

Yes. We opened it up and Dr. Bickel had his difficulties. There was more comminution than was obvious on x-ray examination.

Dr. Bickel:

Four days after reduction the fracture had slipped and open reduction and internal fixation were necessary.

Dr. Detenbeck:

A subsequent roentgenogram taken three months after the fracture (Figure 3) revealed a good result. The cast was then removed and the patient started weight-bearing.

Dr. Bickel:

I believe that one has to be cautious in interpreting this as a good result at this early date, as one can see from the checkup roentgenograms that there appears to be a little valgus of the astragalus in the anteroposterior and the lateral views, and the posterior malleolus does not appear to be perfectly reduced, though it seems to be united. I believe that time will have to tell how well this ankle is going to hold up. Not necessarily referring to this metal, but in regard to all metal around a joint, I would be interested in opinions on what to do with it. Should it be removed? What do you think, Dr. Peterson? Would you leave this metal in place?

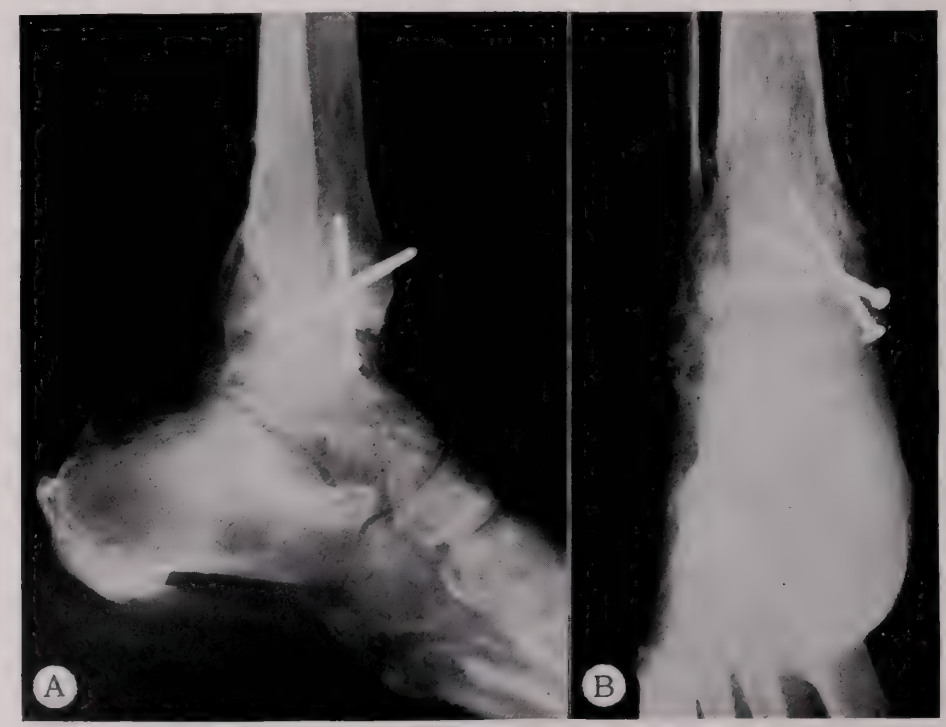

Fig 3 (Case 1)—A and B, Appearance three and a half months after open reduction and internal fixation.

Dr. Hamlet A. Peterson:*

Unless the patient is quite elderly, I think it should come out. It has served its usefulness for one purpose. Possibly it could act as a focus of infection if the patient had septicemia or something of this nature. Also, it might be a factor in any future degenerative or traumatic arthritis. In general, I think that the metal should be removed in the fairly young patient.

Dr. Bickel:

Regardless of whether the patient has symptoms?

Dr. H. Peterson:

Yes.

Dr. Bickel:

How do you feel, Dr. Janes?

Dr. Joseph M. Janes:†

I have never taken screws out unless the head of the screw is subcutaneous and is bothering the patient.

Dr. Anthony J. Bianco, Jr.:‡

I feel the same as Dr. Janes. Particularly with screws, I do not see any reason for removing them unless they are causing trouble.

Dr. Bickel:

You are speaking specifically about screws in the medial malleolus now?

---

*Instructor in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

†Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

‡Assistant Professor of Orthopedic Surgery (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

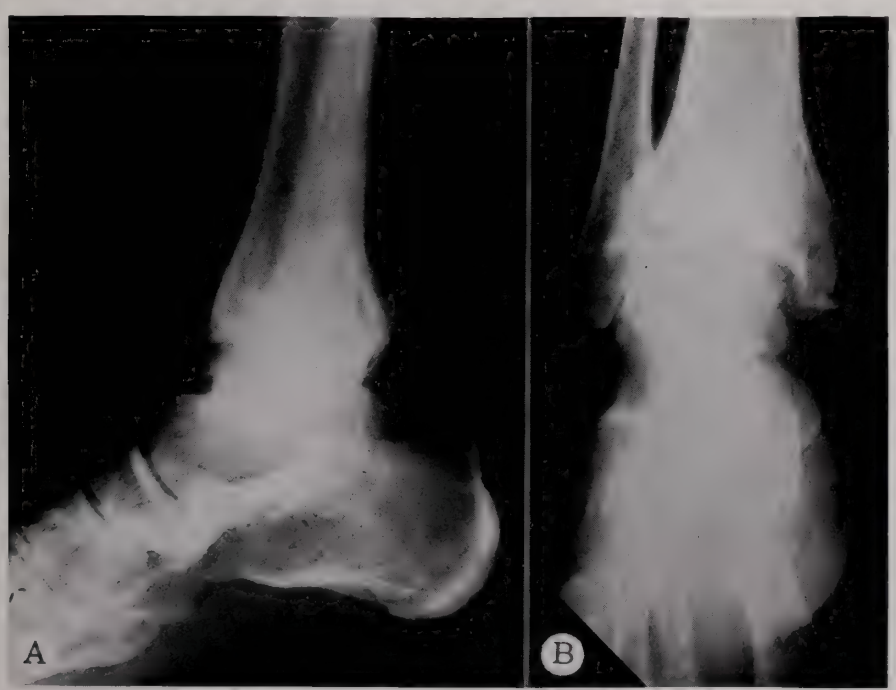

Fig. 4 (Case 2)—A and B, Right ankle 22 months after fracture and open reduction of medial malleolus, showing traumatic arthritis.

Dr. Bianco:

Yes. The ones I have removed have been removed because the screw head was under the skin and was bothering the patient.

Dr. Paul R. Lipscomb:*

It looks as if the one screw that is lying diagonally might give some trouble. I don't know.

Dr. Bickel:

Well, we have two opinions: leave the screws in place, and take them out. I let sleeping dogs lie.

Dr. Coventry:

I feel that today, with the use of vitallium, there is no need to take the screws out unless there is something factitial that could be explained by their presence. Incidentally, taking out some of these screws is not easy. The one placed posteriorly at the time of open reduction in this case might be difficult to remove and some damage might result. I had to remove some like this in the process of doing an ankle arthrodesis not long ago. To get the screw out, I had to retract the posterior tibial nerve. When the screw was put in, the nerve was out of the way, but by the time I got to it it was over the head and the patient had a traumatic neuritis for many months afterward. So it isn't always a simple task to remove some screws.

*Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

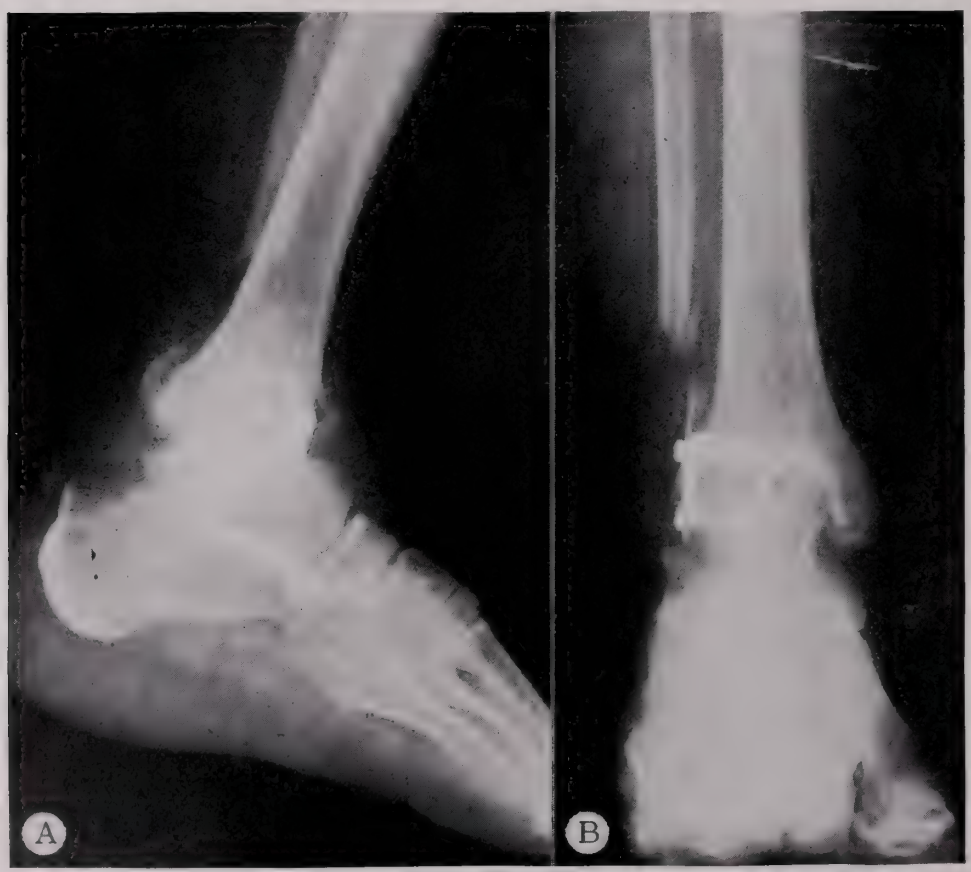

Fig. 5 (Case 2)—A and B, Appearance 11 days after Royal Air Force type of arthrodesis was performed.

Dr. Detenbeck:

Case 2 is that of a 58-year-old rabbi who fractured his right ankle in January 1966. He was treated by his local physician, who did an open reduction of the medial malleolus. Pain in this ankle joint was present postoperatively and continued until August 1967, when the screws were removed from the medial malleolus. This did not relieve his discomfort and he was seen here for evaluation in November 1967, almost two years after the original fracture. Roentgenograms at that time showed marked degenerative changes in the ankle and he was advised to have an ankle arthrodesis (Figure 4).

Dr. Bickel:

This looks as if he had not only the fracture you described but also some degree of tibiofibular diastasis. He seems to have some lateral shift of the talus. Again, Dr. Coventry, it looks like a broad talus, doesn't it? And the medial malleolus is better sized than in the first case, but the talus is broader than normal. I think I can see a modest shift of the talus to the outer side of the mortice. Disruption of the articular cartilage seems obvious. The patient has a marked limp and much ankle distress. Would anybody disagree with doing an arthrodesis?

Dr. Detenbeck:

On November 20, 1967, a modified Royal Air Force arthrodesis of the ankle was performed. This type of arthrodesis uses the distal part of the fibula as a graft to span the site of arthrodesis after freshening and alignment of the joint. Figure 5 shows internal fixation 11 days after the arthrodesis. A short leg cast was applied. Figure 6, taken after removal of the

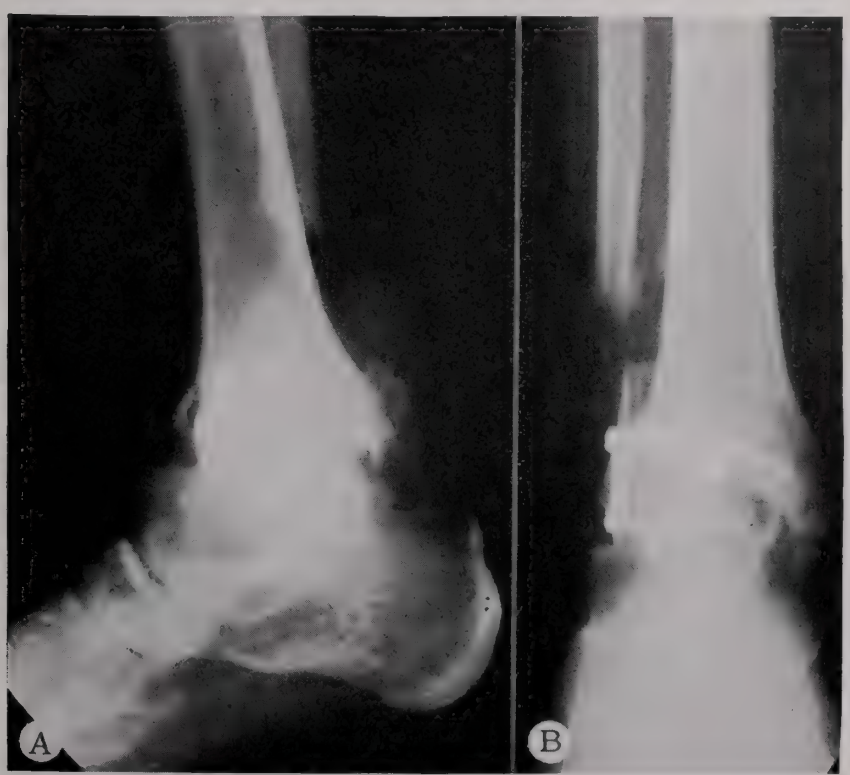

Fig. 6 (Case 2)—A and B, Appearance 4 months after Royal Air Force type of arthrodesis.

cast three and one-half months postoperatively, shows that the ankle apparently was solid. A double iron upright brace was applied.

Dr. Bickel:
